

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

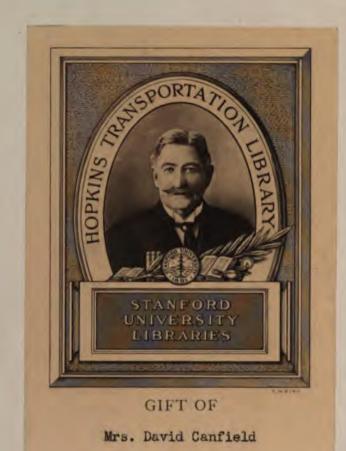

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### **About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

### SPECIAL SUBSCRIPTION OFFER

FOR

# The Horseless Age

To new subscribers we will send THE HORSELESS AGE for one year for \$2 and send gratis (postage prepaid) "Operation, Care and Repair of Automobiles," by Albert L. Clough.

F you use a motor car as a daily means of conveyance—if it is a necessity to your daily work—you will find our book of the very greatest value. Its various chapters have been prepared by specialists, and the entire book has been edited by Albert L. Clough.

As its title indicates, it deals most comprehensively with every phase of operation, care and repair—it not only thoroughly describes the various elements of a motor car, and the functions performed by them, but also explains the derangements to which they are liable, and their remedies.

It will help you solve problems which will sooner or later demand your attention—the proper housing of a car, safe storage and handling of gasoline, cold weather precautions, putting up a car for the winter, grinding in valves, repair of punctures, and many others.

The total contents fills more than three hundred and fifty octavo pages containing an equivalent of six hundred words each, and every chapter which calls for illustration is copiously illustrated with sharp, clear line cuts and half-tones.

Realizing that many owners of automobiles are very busy men, and may not have time to carefully read the entire book in the manner one would study a text book, we have provided it with a very complete index which facilitates reference to any particular subject. The book also contains a vehicle speed chart and a gear ratio table.

### Exhaust Gas Analysis.

By Albert L. Clough.

Most of the readers of The Horseless Age will recollect the publication in the issue of January 1 and January 8, 1908, of an abstract of a paper by the eminent authority Dugald Clerk upon "The Principles of Carbureting as Determined by Exhaust Gas Analysis." This article treats of the information which is afforded as to the quality of fuel mixture furnished a motor from a determination of the chemical constitution of the exhaust, and is well worthy of a careful rereading by all who are interested in the problem of carburetion.

Since this paper was published the interest taken in carburetion by carburetor manufacturers, automobile builders and by the motoring public has immensely increased, and its solution is now being sought in a much more scientific spirit than formerly.

It is safe to say that exhaust gas analysis will be very largely resorted to in the future, as furnishing the most reliable criterion as to the quality of fuel mixture being furnished any given motor, and that this chemical method of gaining information upon the carburetion question will become one of common application in carburetor factories and automobile plants.

A brake test of a motor furnishes sufficient information as to its output, and a brake test during a period of time, in conjunction with corresponding measurements of fuel consumed, suffices to determine the fuel efficiency of the motor. However, unless determinations of exhaust gas constitution accompany such a test it is impossible to be certain that the fuel efficiency realized is the highest attainable from that particular motor. There may be a considerable rejection of carbon monoxide, a considerable emission of other unburned fuel in the form of hydrocarbons or hydrogen, and there may be an undesirable excess of oxygen.

### CARBON MONOXIDE.

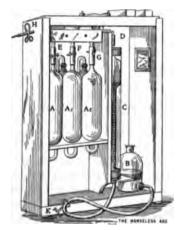

Carbon monoxide is valuable fuel, being a chief constituent of producer and blast furnace gas. It is the result of the incomplete oxidation of carbon, and its complete combustion to carbon dioxide sets free about 30 per cent. as much heat as does the complete oxidation of the same weight of carbon. Its rejection unburned in the exhaust is not only so much waste of good fuel, but its poisonous properties render it a serious menace to health. As the use of motor vehicles increases it may be expected

that the emission of carbon monoxide may be recognized by law as dangerously unsanitary, especially in crowded city districts, where automobiles congregate in large numbers.

The rejection of unburnt gases or vapors rich in hydrogen is an obvious waste of the grossest kind, for hydrogen possesses a thermal value roughly four times as great as that of carbon.

### EXCESS OF OXYGEN.

If a too great excess of oxygen be present in the exhaust there will be nearly five

THE ORSAT APPARATUS.

times that quantity of excess nitrogen there, and the presence of this large quantity of gas, which is inert so far as the combustion is concerned, necessarily reduces the maximum temperature attained during explosion, and acts, in a way, to reduce the effective volume of the cylinders.

Exhaust gas analysis not only throws light upon carburetor performance, but may also furnish information as to the efficacy of ignition devices, and as to whether these are advantageously placed in respect to firing the charge most effectively.

It is not a very difficult matter if the proper apparatus is at hand for any intelligent person to make at least partial analyses of exhaust gases. There is no necessity for sending exhaust gas samples to a regular chemist unless some very unusual determination is required. A gas analysis apparatus of the Orsat type in the hands of an ordinarily careful person will give suffi-

ciently close indications of the carbon monoxide and excess oxygen present with very little labor. The Orsat apparatus is frequently to be found in the possession of the steam engineering departments of large plants, where it is used for analyzing the chimney gases leaving the boilers, with a view to effecting economies in coal consumption.

### THE ORSAT APPARATUS.

The principle of this apparatus is as follows: A sample of the gas to be analyzed, of a known volume at known pressure and temperature, is placed in a graduated glass cylinder or burette. Means are provided for transferring this measured quantity of gas successively into vessels containing certain solutions. One of these solutions absorbs the carbon dioxide present, and after the gas has been in contact with this solution for a sufficient length of time it is drawn back into the measuring burette, and the difference between the volume then present and the initial volume represents the proportion of carbon dioxide in the sample. The same procedure is carried through to determine the oxygen present by transferring the remainder of the sample into the presence of a solution adapted to absorb it, and then returning it to the burette, when the difference in volume before and after absorption gives the proportion of this gas. Exactly the same manipulation is resorted to for the purpose of determining the proportion of carbon monoxide present. After these three gases are removed from the sample by absorption the remaining volume consists of nitrogen and whatever combustible gases or vapors (other than carbon monoxide) the sample may have contained. These combustibles require subsequent treatment in another apparatus.

A portable form of the Orsat apparatus is shown in the accompanying figure. Here C is the measuring burette, usually of 100 c. c. capacity, which is surrounded with a water jacket that tends to prevent changes of temperature. A, A<sub>1</sub> and A<sub>2</sub> are double pipettes, the rear bulbs of which are only partly shown in the background, as are also the connecting tubes just below the bulbs. The outlets of the back bulbs are fastened into the necks of extensible rubber bags. From the upper end of the burette is taken off the capillary tube D, which turns at a right angle and passes horizontally over the three pipettes, giving off branches which communicate with each. These branches are closed, respectively, by the pinch cocks E, F and G. The extreme end of the horizontal capillary tube is closed by the pinch cock H. B is a bottle of water connected to the bottom of the burette by means of a rubber tube, upon which the pinch cock K may be closed.

### METHOD OF MAKING TEST.

The sample to be analyzed may be collected in a metal cylinder by allowing the exhaust to circulate through it until the air originally contained in it has been entirely displaced. The connection can usually be made at the cut-out valve or with the piping used to operate an exhaust horn. If the sample is to be immediately operated upon a rubber gas bag may be used to collect it in, but the gas must not be allowed to enter the bag at too high a temperature.

Before introducing the sample into the burette the cock H is opened and the bottle B raised until the burette and the connecting tubing are filled with water. H is then shut and the vessel containing the sample is attached to this tube. H being opened and the bottle B lowered, about 100 c. c. of the sample is sucked into the burette C, taking the place of the water, which runs back into the bottle B. H is then closed and the amount of gas in the burette is adjusted so that it measures exactly 100 c. c. when the bottle is held so that the level of the water therein is exactly the same as the water level in the burette.

The double pipette A contains a solution of caustic potash, and the sample is first admitted to this vessel by opening the cock G and raising the bottle so that the entire measured volume of gas in the burette is forced thereinto. A portion of the liquid in the front bulb of pipette A is thereby forced over into the back bulb, and the displaced gas in the back bulb partly fills the rubber bag. Glass tubes arranged in the front bulb are exposed to the sample by the recession of the solution and aid in effecting absorption. The carbon dioxide present in the sample unites with the caustic potash to form potassium carbonate, and thus disappears. By raising and lowering B the gas may be moved into and out of A, and after a few such manipulations the levels in B and C should be made to coincide, and a reading should be taken after time has been allowed for the walls of the burette to clear themselves of water. This preliminary reading having been noted, the gas should again be entirely forced into A and the same procedure repeated, and the levels of the water in B and C again equalized. If the reading then obtained is the same as the preliminary reading all the carbon dioxide has been removed, and the difference between the volume now noted and 100 is the percentage of carbon dioxide in the sample. If the two readings do not agree the sample should again be forced into A and returned to C until agreement between successive readings is obtained. Cock E is then shut, with the water levels in B and C equalized, and cock F, opening into pipette A1, opened. This pipette contains a solution of potassium pyrogallate,

rendered slightly alkaline, which has the property of absorbing oxygen. The remainder of the sample is forced into and out of this pipette, exactly as above described, until two successive readings of the gas remaining in the burette C agree—the water levels in C and B always being the same when a reading is taken.

After absorption in A<sub>1</sub> is complete the difference between the then reading and the reading after the absorption of the carbon dioxide gives the percentage of oxygen in the sample. Cock F is then closed and cock G, connecting with pipette A2, is opened. This pipette contains a solution of acid cuprous chloride, and has the property of absorbing carbon monoxide. The remainder of the sample in the burette is forced back and forth into this pipette until successive readings check very closely, and the difference between the reading thus arrived at and the reading after complete oxygen absorption is the percentage of carbon monoxide in the sample.

The portion of the sample remaining in the burette after these three determinations consists mainly of nitrogen, but there may be mingled with it combustible gases which have failed to burn within the cylinder. It appears, however, that there is little or no hydrogen, hydrocarbons or compounds of the marsh gas series present when there is little or no carbon monoxide found in the exhaust, and that, on the other hand, as the carbon monoxide content increases the proportion of combustible gases increases. For ordinary purposes, therefore, it is not necessary to determine the amount of combustibles in the exhaust, but it may safely be assumed that if carbon monoxide is present in more than minute amounts combustible gases are also being wasted at a rate somewhat proportionate to the amount of carbon monoxide rejected. The determination of the carbon monoxide content of the exhaust is thus the main thing, and the presence of this gas is conclusive evidence of the incomplete combustion of carbon. It is a pretty sure thing that if the carbon in the mixture is imperfectly burned the hydrogen will also be partly rejected unconsumed.

### UNBURNED COMBUSTIBLE.

It is possible, however, to determine the amount of combustible which is left mixed with nitrogen in the Orsat apparatus. The remainder of the sample may be transferred to an explosion bulb and a known volume of pure oxygen added to it, the total volume being measured. The mixture is then fired by a jump spark, and from the reduction in volume and the known amount of oxygen added the volume of combustible may be obtained after the carbon dioxide produced by the combustion has been allowed for. This determination, if required, as is unlikely to be the case, may with advantage be left to a professional chemist.

The determination of carbon monoxide is, however, an easy matter, and furnishes nearly all the information needful as to the degree of completeness of the combustion. A too great excess of oxygen is also plainly indicated, if present, by the same test. Some excess is, of course, to be expected.

### The Automobile Insurance Field.

By J. E. JENNINGS.

The automobile insurance field is evidently regarded as worth cultivating by the various companies, fire and casualty, which are looking for paying business. The subject of rates is, of course, paramount with the managers of the insurance companies. The cutting of rates, for instance, is not viewed with favor, and there is a petty war between some of the companies, as previously mentioned in The Horseless Age.

The manager in New York city for the American Fidelity Insurance Company of Montpelier, Vt., has sent out a new schedule of liability rates formulated by the company. These rates are based upon the insurable horse power, and start, for steam and gasoline pleasure cars, at \$30 premium for 12 to 16 horse power, and for each additional horse power thereafter the rate is advanced a dollar. These rates are, it appears, quite a little lower than the figures of nearly all other companies writing this class of hazard, particularly as regards the high powered cars, as the company claims that, based on its experience, the loss ratio on the larger cars is not as high as on the higher powered cars. It is noted that the company makes a further reduction of \$5 from the above named rates for cars which are operated outside of Greater New York, Boston and Chicago, and has introduced a new feature by quoting a premium rate of \$20 for motorcycle liability.

Following the promulgation of the American Fidelity's schedule a meeting was held at the offices of the Ocean Accident Insurance Company in New York by representatives of casualty companies writing automobile collision insurance for the purpose of arriving at some agreement as to the basic rate to be charged and the extent of coverage to be given. Nothing definite was done, but the subject was thoroughly discussed. The result of further conferences is shown in the new schedule printed in The Horseless Age of June 16.

The Travelers Insurance Company of Hartford, Conn., has begun to write automobile collision damage insurance. The Commercial Union Assurance Company began last month to write automobile insurance business.

FIRE INSURANCE COMPANIES INTERESTED.

The fire insurance companies intend to have a share of the automobile insurance crop. The Board of Fire Underwriters at Chicago, Ill., recently ruled that insurance on automobiles is fire insurance. Heretofore this form of insurance has been classed as "inland marine," inas-

much as the policy used covers collision, transportation and theft. The Legislature of Missouri has amended the law governing fire insurance companies so as to permit them to make all kinds of insurance on automobiles. Last year the companies were notified that they must stop the issuance of policies which indemnify against loss by theft in addition to the fire loss, because the law as it stood did not contemplate the first named kind of insurance.

So important, or, rather, so rich, is the automobile insurance field regarded by insurance companies that in a couple of cases steps have been taken to have the companies' charters amended by legislative enactment so that they could secure a share of the business. The Ætna Fire Insurance Company of Hartford is one of these companies.

#### BONDING CHAUFFEURS.

The bonding of chauffeurs is advocated by insurance men. It has been suggested that every chauffeur should be required to provide the bond of a surety company in a penalty of not less than \$2,500, upon which bond, to the amount of its penalty, a right of action should exist in favor of anyone sustaining damage to person or property by the negligence of the chauffeur. This, it is argued, would open a new field for activity to the surety companies, and the idea should be acted upon by them. It is claimed by those in a position to know that any company now writing bail bonds for the owners of automobiles could with little or no difficulty build up a good income from the sale of these bonds for chauffeurs to the drivers themselves. This tentative proposition has not so far been pushed, but perhaps it may be incorporated in a bill to be presented to the next meeting of the Legislature.

Auto Imports of Last Fiscal Year. The United States during the last fiscal year, which ended on June 30, imported 1,987 automobiles, valued at \$4,311,295.99, as compared with 1,415 cars, valued at \$4,111,225.43, during the fiscal year 1907-8, and 1,435 cars, valued at \$5,099,005.87, during the fiscal year 1906-7.

Wheeler & Schebler, Indianapolis, Ind., have donated a cup to be contested for on the Indianapolis speedway. It is said to be the largest trophy of the kind ever made, being about 81/2 feet high and weighing some 500 pounds. It was made by Tiffany, of New York, and is decorated with appropriate automobile designs. The trophy will be competed for in international stock car events on the speedway, and will become the permanent possession of the company winning it three times. It will be exhibited in a number of the large cities. starting with Detroit, where it will be shown during the week preceding the start of the Glidden Tour.

### Manufactured Versus Assembled Cars.

By CHESTER S. RICKER.

One frequently hears the statement that "our car is built entirely in our own shops." The question which immediately arises is, what a advantage is it to the buyer when cars are so manufactured? To consider this question fairly, we must look at both sides of the subject and consider what is meant by the terms "manufactured" and "assembled."

#### MANUFACTURED CARS.

Shall we say that one car is manufactured and another is not, merely because the maker of the former makes his own castings while the latter does not? I do not think so. It depends on where the machine work is done, for, whether one does or does not make his own castings, he must do all his machine work if he aspires to the reputation of being a manufacturer. Further, outside foundries which specialize can do much better work than the average automobile manufacturer who attempts it. So, unless we consider the latter type as representative, we might as well go back to the steel manufacturer and the remainder of raw material producers. Besides, it is the accuracy of the machine work which determines those advantages most sought for by the buyer, such as smooth running, long life and interchangeability. Furthermore the prime cost depends very little on the price paid for the castings, as compared with the expense of the machine work which follows. An automobile chassis upon which all machine work is done in the factory of the builder may therefore be called a manufactured car.

### ASSEMBLED CARS.

Opposed to this we have the so-called assembled car. That an assembled car can be made a success is beyond question, for at least a dozen of the prominent manufacturers of today began by assembling and even continue to partially assemble their cars. Of assembled cars there are two kinds, viz., cars built from parts obtained in the open market, and cars built by some well established firm, the volume of whose orders requires the co-operation of the various parts makers. The former type is the one which has brought the assembled car into disrepute. As a rule, after a few lots of cars are sold it is almost impossible to get replacements. The reason for this is that such companies are not able to invest large sums of money in the spare parts department, so, together with the buyer, they are at the mercy of the parts maker. Furthermore, if a replacement is required while touring it might be weeks before one could get the part. The inability to quickly obtain interchangeable spare parts has probably done more harm to the assembled car's reputation than any other one thing. The highest type of assembled car is one the parts of which are made by parts makers but the elements of which have been specially designed by one head and form a harmonious whole.

### ADVANTAGE OF MANUFACTURED CARS.

Following are the principal advantages which are claimed for the manufactured car. First, the builder has the deepest interest in every detail during construction, while, on the other hand, the parts maker may not have any particular interest in the assembled machine, especially if the car is produced by a small and obscure company. But the contrary is equally true, as may be seen from advertisements of leading parts makers.

Since the manufactured car is designed and constructed under the supervision of the factory staff we have a unified product. Slight changes which tests and tryouts indicate to be desirable can very easily be made, a refinement which would be impossible if the parts were bought in the open market. Thus each element of the design can be made to harmonize with every other and the whole. Likewise, the material entering into the makeup of the machines can more easily be checked as to quality.

As a large outlay for machinery is necessary for the manufacture of a car, only those firms which have good financial backing can afford to equip a factory to produce every part themselves. Once the investment is made there is every incentive to keep the plant going and make the investment which it represents pay for itself. Hence, although it requires more capital this plan conduces to a healthier and more energetic organization, because there is a factory behind it. With this we have essentially what every maker is striving for, viz., permanency.

Where a concern is once permanently established the buyer does not have to ask "What will I do in a year or two when I want a replacement?" The manufacturer could answer this question by saying that if he did not have the parts in stock he had his own patterns, jigs and dies, so that he could give the customer what he needed. The advantages of the manufactured car can be summed up in three words: replacements, interest and permanency.

### THE ASSEMBLED CAR.

"There are tricks in every trade," according to an old saw, which came to my mind recently when I learned that two identical assembled chasses sold by separate firms differed by over a thousand dollars in selling price. The costlier had a year's guarantee, but was it worth the premium? However, recently it was my fortune to visit the factory of a popular car built on the assembling plan. My first inquiry was as to the methods adopted to protect the buyer. After thorough investigation of these I was convinced that a car so assembled is on a par with cars of its class that are "manufactured." A de-

scription of the methods of this assembling firm may be of interest.

The cars are designed at the firm's factory, and by their own engineers. The experimental models are built and tried out, and any changes deemed necessary are made before even one is delivered to the public. The company own all their own patterns, jigs and dies, and their orders are so large that the parts maker has to make the smallest alteration that the engineering staff may prescribe.

Making its own designs and owning its own patterns, etc., replacements can be produced at some late period when the present model is long out of date and no parts remain in stock. A special lot of spare parts, however, are kept in stock. Also, it should be noted here that the engineering as well as the bookkeeping department keeps a careful record of the replaced parts in each model. If at any time more than 2 per cent. of the models already on the road require replacements of the same parts, the reason is found out and the defect remedied. With respect to ability of furnishing replacements, this firm at least is equal to the best manufacturers. The company have from fifteen to twenty inspectors in each factory where parts entering into the construction of their car are made. These inspectors, being paid by the parent company, and having no interest in the manufacturing firm, subject the parts to more severe tests than they might in their own factory.

Finally, the most serious question which confronts the buyer is, Which car has the most money value? The question which now confronts us is whether the assembler can give the buyer as good a bargain as the manufacturer. From actual statistics this firm found that even paying the parts maker a profit the motor and transmission parts cost no more than if built by them. The reason for this is evident when one considers that the overhead charges would be much higher per motor if it were placed on this lot of motors alone than if spread over those of a dozen other firms. Frames, axles, etc., are made to special designs by the parts makers for the majority of large manufacturers, so that in this respect the assembled car does not differ from the built one. In my opinion, therefore, the car assembled as outlined in this article is the equal of the manufactured car with regard to money value and satisfaction to the buyer, for in both cases we have the three requirements-replacements, interest and permanency-fulfilled.

A publicity item is making the round of the press to the effect that a Kansas banker bought a certain make of car after having seen only a photograph of the machine, "so fascinated was he by its appearance." The banker probably realized that his knowledge of mechanical constructions was a vanishing quantity, and that an examination of the "innards" of the car would not have aided his judgment in the least.

# The Work of the Examiners and Investigators of the Automobile Department of the Massachusetts Highway Commission.

### By H. H. Brown.

The automobile law of Massachusetts makes it the duty of the State Highway Commission to register the automobiles used within the State and to issue licenses to the operators thereof. While the Massachusetts motor vehicle law is quite specific in the more important details, the circumstances vary, and there are many points which are not referred to. The Highway Commission is, however, empowered to make rules which do not conflict with the general provisions of the law, and among the duties of the commission is the issuing of licenses for both private and professional operators and the revocation of same for cause.

To assist the commission in these duties the law provides for examiners and investigators. The duties of these officers are to examine and pass upon the fitness of the applicants for licenses and to investigate all automobile accidents with a view to placing the blame, and also flagrant infractions of the automobile laws. The commission is kept informed of accidents and cases of infractions of the automobile law from three sources, viz., by direct report to them, by court records, which according to law must be reported to them, and by the services of a press clipping bureau.

The time of one of the investigators, who has his headquarters in Boston, is given solely to the investigation of violations of the law and accidents. Another investigator looks after the accident cases in the western part of the State as well as the examination of applicants for operators' licenses. The time of two others, with headquarters in Boston, is almost exclusively employed in the examination of operators. These officers are given the powers of police officers and constables, and may testify before the commission, which sits as a court in cases of violations of the automobile law.

The largest part of the work of the officers is the examination of applicants for professional operators' licenses, or, as the law reads, "operators for hire." Private operators are required to undergo an examination only in exceptional cases, as when they are under 16 years of age, the fact as set forth on their applications being deemed sufficient warranty of their fitness to operate. This was also formerly the case with professional chauffeurs, but as can be readily expected this leniency was in many cases abused and a system of examinations was made necessary. This examination comprises a written or theoretical part and a practical examination in the driving of a car. Originally the written examination consisted of a set of twenty-five questions, nine of which were on the operation of a garoline motor, and the re-

mainder on the automobile law and rules of the commission. It was found that answers to these questions were learned by many of the applicants from others who had taken the examination, therefore at present about ten questions are asked, the majority having reference to the automobile law and the rules of the road, only one or two being on the operation of a car. These questions are eminently practical, and no intelligent person need have fear of failing in this part of the examination if he has read the pamphlet on the laws and the rules of the commission which are furnished to each applicant for a license. The list of questions is frequently changed and a fair example is as follows: What is considered prima facie evidence of excessive speed in the built up portion of a town or city? State three infractions of the automobile law which may be punished by imprisonment. What causes back firing in the carburetor of a gasoline motor? What would you do in descending a hill if your brakes failed to work?

At the time set for the other part of the examination the applicant must report at the offices of the commission with a car with the operation of which he is familiar. Then, accompanied by an examiner, the operator is instructed to drive over a route passing through a congested section and embracing the descent of a steep hill. Without warning, the examiner instructs the operator to stop at a letter box or other similar point and to back the machine around the corner of a side street, when a return trip to the commission's office is made. During the examination the examiner has noted the care exercised by the operator on approaching street crossings, in selecting a time for the use of the horn, the use of the brake in descending the hill and the observance of the rules of the road, especially in rounding corners. It is also noted by the examiner whether the operator is able to concentrate his attention on the surrounding traffic instead of on the control mechanism of the car. Cautious driving, if carried to excess, is looked upon with more favor by the examiners than so-called showy driving, even if the applicant shows considerable skill in the handling of the machine.

The Danish A. C. held an endurance contest "all around Zealand" over a course 423.8 km. (265 miles) in length. The contest was open to touring cars owned by members of the club. The cars were started at half past 3 o'clock a. m., and none of the contestants were allowed to check in at the finish before 5 o'clock p. m.

The Government authorities at Bombay have made arrangements with a French firm to place 100 first class and fifty second class taxicals on the streets of the city, and a similar arrangement has been made with regard to Madras. This does not preclude other owners from putting taxicabs into service.

BRENTANO'S, 37 Avenue de l'Opéra, Paris.

COMMUNICATIONS.—The Editor will be aleased to receive communications on trade topics from any authentic source. The correspondent's name should in all cases be given as an evidence of good faith, but will not be published if specially requested.

Address all communications and make all checks, drafts and money orders payable to THE Horse-LESS AGE, 9-15 Murray street, New York.

Entered at the New York post office as secondclass matter.

One week's notice is required for change of advertisements.

Telephone: 7195 Barclay.

Cable: "Horseless." New York and London. Western Union Code.

### Injudicious Haste in Marketing New Models.

A former Chicago automobile dealer, who has spent the last two years abroad and has just returned to his home city, announces a determination to put the automobile business on a higher plane, and in an advertisement in a Chicago Sunday paper gives an outline of his plans. In making an analysis of the automobile business in this country he observed three serious evils, for which he believes he has found effective remedies

A comparison of the best American and European cars has led him to the conclusion that the latter are considerably better than the former, and this because the European manufacturers work more slowly, develop their cars step by step, and do not experiment at the expense of the public. Another thing with which he finds fault is the high selling expense. He says that he can see no reason why a dealer disposing of 100 cars in a year should need to spend from \$65,000 to \$75,000 annually in running his business, and why a car costing

\$1,500 to manufacture should have to be sold at \$4,000 or more to the public. The "commission evil" between chauffeurs and people who sell automobile supplies is also scored. We will consider here only the first of the points made.

The comparison of American and European cars would have been more correct had it been based on average cars. instead of the best of each class. It is certainly not fair to imply that the best American manufacturers throw immature models upon the market and experiment at the expense of the public. They certainly do not. Of course, such things are being done at present, and by manufacturers, too, who, on account of very large output, occupy a very prominent position in the industry, but they are generally newcomers, and certainly cannot rightly be classed among the best manufacturers.

We have had quite a number of examples in recent years of cars being designed "from the bottom up," models built and duplicates delivered to the public within six months' time. The manufacturing plans are generally completed at the time the designing work is begun, and practically no time is left for extended road trials to bring out any inherent faults in the design, so as to be able to correct them before the manufacture of the first lot of cars is begun. Under these circumstances it is not surprising that we frequently hear of annoying delays in the delivery of new models, owing to some part having been found inadequate, necessitating new dies or patterns being made involving serious financial

One of the reasons for this haste is that promoters of new companies will not admit the necessity of experimenting. Such an admission might "scare off" both prospective investors and prospective agents and buyers. But the advisability of giving each feature of a new car a thorough tryout before proceeding to order parts is well shown by the policy pursued by most of the old established manufacturers. They usually make only minor changes in their models from year to year; nevertheless, they submit their new models to road tests often extending over several thousand miles, to bring out any flaw that may exist in the design. If such searching tests are necessary in the case of models which are merely changed in detail, how much

more necessary they are in the case of absolutely new designs!

However, it is not merely because the dollar looks more omnipotent to the American than to the European-as the above quoted dealer asserts-that the American manufacturer proceeds more hastily than his European confrère. The rapidly changing market conditions in this country undoubtedly have a strong influence on the method of developing and marketing new models. This is partly due to the fact that entirely new markets are still being opened in the United States, new sections of the country being invaded by the automobile, and new classes of the population becoming converted to its use. In the chief automobile countries of Europe the markets seem to have been developed to their utmost. This difference accounts for the present great activity of the automobile industry in this country, in contrast with the relative stagnation in the industry abroad. When new sections of country or new classes of users have to be supplied slight changes in the types of vehicles must often be made, and whoever is the first to offer a suitable vehicle will find the best outlets. Consequently, the haste in developing new models is partly accounted for by the fact that in this country the automobile business is still in the ascendancy, while abroad it has passed the zenith. After market conditions have once become settled in this country there will be less haste in getting new models on the market, and the evil consequences of such haste will be avoided.

### Authority of Cities to Regulate Taximeters.

That taximeters should be placed under some form of legal supervision in order to insure a reasonable degree of accuracy of the charges for transportation is generally conceded. The taximeter is in the nature of a measure and should be subject to inspection, the same as are weights and measures used in the ordinary barter and sale of commodities. However, it is something more than a measure, and unless a city possesses express authority to regulate measuring instruments combined with a mechanism of mathematical computation of either prices or charges, any ordinance passed under a charter power to regulate weights and measures will be void. In

other words, legally the taximeter cannot be placed in the same category with the ordinary scales and measures which are to be found in stores.

New York city was the first municipality to enact a comprehensive scheme for the regulation of taximeters. The city charter expressly provides that the board of aldermen shall have power to pass ordinances in relation to the inspection or sealing of weights and measures (see Sec. 49, p. 39), and it would seem, perhaps, on first thought, that this charter authority is broad enough to give legality to the action of the city. The above applies equally to other cities in the United States. It will be particularly noticed that the charter limits the powers of the aldermen to the regulation and inspection of the two named classes of instruments. Inasmuch as the taximeter is something more than a measure, to wit, a measure plus a calculating apparatus, it does not legally come within the statutory authority of the city. Municipal corporations have only those powers in respect to police regulations of this character which are expressly conferred by the charter or some other statute. There is no general authority under the police powers to enact such ordinances restricting the use of property.

The authority of municipalities to regulate weights and measures, by providing for their inspection, necessarily implies that there must be a comparison made with some standard established by law. There is now no standard established by statute for the purpose of testing taximeters, and it is not within the power and authority of an inspector to establish such a standard for himself. The standard for the purpose of testing weights and measures must be established by law. All of the various States have established a standard foot, yard, etc. The United States Government has also established standards of measure which have been copied by the States. The establishment of a standard of comparison must, therefore, necessarily precede the establishment by law of a system of inspecting measures.

The above assertions are borne out by the decision in the case of Parker v. Webb, 121 N. W. Rep. 322, which holds that the charter provision of the city of Detroit, authorizing the common council to regulate weights and measures to be

sealed by the city sealer, so as to be made comformable to the standards of weights and measures established by the general laws of the State, does not authorize an ordinance requiring the city sealer to determine the accuracy of computing devices on scales of merchants by which the value of the goods weighed is to be determined.

The taximeter being a new kind of measure will require a new kind of standard, if we are to have this instrument officially inspected and sealed. The remedy is in the Legislature.

# Special "Low Wattage" Tires for Electric Vehicles,

Possessing a radius of action not more than one-sixth that of the average gasoline car of the same type, the electric vehicle must be so designed that the energy stored in its battery shall be expended with the utmost economy. Particularly is this the case in view of the fact that as many hours are required to replenish the battery charge as are minutes to refill the gasoline tank. Not only are all moving parts of the electric car mounted upon anti-friction bearings, the greatest care taken to eliminate friction in the transmission and the utmost attention paid to flexibility of the running gear, but special pneumatic tires have been developed for this service which greatly reduce the traction resistance and economize the charge in a very marked

These tires are exceedingly thin walled, and so constructed as to dissipate but very little energy in the form of internal work. They are mostly of a special single tube or "hose pipe" style, although they have recently been developed in the conventional detachable type. "Low wattage" tires, as they are called, by virtue of their extreme resiliency, conserve a large amount of energy which regular tires dissipate, and the mileage per charge of a vehicle equipped with them is very considerably augmented.

The low speeds at which electrics are ordinarily operated, and the generally easy service which they are put to, as compared with gasoline cars, render possible the application to them of these thin walled and somewhat fragile tires, and many of the high mileage records which are reported are made possible through their use. They are, however, extremely liable to puncture and to other forms of failure.

The owner of an electric vehicle in choosing his tires is called upon to make

the following decision: Whether, by the use of low wattage tires, to increase his mileage and lessen his outlay for electric current, and at the same time subject himself to the liability of delays due to punctures on the road and to the additional tire cost arising therefrom, or to use standard tires and be satisfied with a more moderate mileage and the assurance of a comparative freedom from tire troubles.

It is quite possible that certain circumstances of use might render each of these courses in turn advantageous. Where electrical energy commands a very high price, and road conditions are favorable to tires, it might prove a paying proposition to use low wattage tires, while under conditions of very cheap electricity and roads destructive to tires the use of standard casings and tubes would be distinctly indicated. It seems quite probable that there is a field for these special tires in connection with the electric vehicle, for with it economy of energy is an all important factor.

The French Minister of Finance plans to raise 9,000,000 francs by placing an internal tax of 5 francs per hectolitre on gasoline of a density less than 0.765, on benzol, benzine and toluene. The same import tax is to be placed on benzol as is now exacted on gasoline.

### Coming Events.

July 4-17-Endurance Test, Automobile Club of Sweden.

July 8-Taylor (Tex.) Track Meet, Taylor Fair Association.

July 10—Santa Monica (Cal.) 200 Mile Road Race, Southern California Automobile Dealers' Association.

### The Scottish Reliability Trials-II.

BY ROY LINDSAY.

WEDNESDAY, JUNE 16. s day's route, covering 173 miles, rised a circular trip from Inverness to the extreme northwest of Scotthen south and east, back again to arting point. About one-quarter of the ice was over well surfaced main roads, e remainder was up and down mounus tracks only open to traffic for some months of the year, the snowdrifts entirely disappearing until the mid-May, Such evidences of civilization am road rollers are never seen in this of the country, as it would be imposfor the machines to get up the hills, besides, there is very little wheel trafne population being more sparse than by other district in Great Britain or nd. The difficulties of the day were ased by the narrowness of the track, after mile only giving barely room ne car to traverse, and the atrociously surface resulted in more punctures on any other day in the week, stopfrom this cause being frequent. As ars traveled in very close order, no than fifteen vehicles were stopped by gle puncture on one occasion, passing stranded car being quite impossible. ne point there was no conflict of opinviz., that for variety of scenery this far outstripped all viewed on any of our preceding years. There was one nuous ascent from sea level for nearly es to a spot 2,000 feet above sea level. was among the Fannich Mountains, from their height are popularly n as the Scottish Alps. Here the cars actually above snow level, which never ly melts so far north, and when the as reached snow was still lying around vas visible in many directions.

timed climb on this day took place minard Hill, 1,775 feet in length, with al rise of 226 feet, the grade varying 13 per cent. to 16 per cent, Every eached the top without trouble. One ar mishap to a car after the timed was due to a punctured float in the retor, which the driver repaired in y-three minutes, but which cost him of nearly eighty marks. Another car ed from breakage of nearly every leaf front spring; that was patched up by and mechanic, but necessarily ind heavy penalization. Another mishat occurred the first day illustrates olly of cars following each other too y in an event of this character. While rsing a rough road covered with loose s, a large one was thrown backward such impetus by the wheel of the ig car that it hit the radiator of the vehicle and caused so much leakage tops had to be made every two hours up with water. A complete new rawas telegraphed for, sent up from on and replaced the leaking one; such though permitted by the rules, meant

not only a penalty according to the time occupied, but also the loss of the whole of the reliability marks that could have been secured for the day and would put the car right at the bottom of the list.

Forty-seven cars secured non-stop records for the day, and in the timed climb most all that had done well on Cairn o' Mount repeated their performances. Despite the severe work, the little cars in Classes A and B were the feature of the day, seven of them obtaining full marks for reliability, a really astonishing feat that was quite unexpected and indicates the enormous improvement that has taken place in small powered machines in the last twelve months.

THURSDAY, JUNE 17.

The route of this day, 1741/2 miles, was quite an easy one compared with the previous day, much of it being alongside of a series of entrancingly beautiful lakes that were joined up artificially eighty years ago, and now bear the name of the Caledonian Canal. Still another timed climb took place quite early in the morning, 34 miles from the starting point, at Glendoe Hill, having a length of 2,940 feet, with a total rise of 390 feet, and an average grade of 13 per cent. Although the average appears easy, much of it is actually steeper, there being several pitches of 20 per cent. grade and a few yards of 22 per cent. The small cars in Classes A, B and C were excused from the climb, and although one or two might have succeeded, it was considered advisable not to subject them to the tests. The sensation of the day at the hill was the ascent made by the 30 horse power Adler, many seconds faster than any other car. Two cars were withdrawn before reaching Pitlochry, the end of the day's

run, these being the 28 horse power Mass, with stripped teeth on the magneto drive, and the 30 horse power Vinot, with a broken inlet valve. Thirty-eight cars obtained non-stop awards for the day.

FRIDAY, JUNE 18.

Another circular route was programmed for this day, from Pitlochry via Grantown and Braemar back to Pitlochry, a distance of 163 miles. There was no timed climb, for which everyone was thankful. The only long, steep hill that had to be tackled was Cairnwell, which proved such a stumbling block to a large number of competitors when ascended last year during a pitiless thunder storm. This year the surface was quite dry, and every car reached the summit comfortably. But the crux of the journey was some 60 miles of by-ways, purposely selected for their narrowness, precipitous descents and corresponding ascents around hidden hairpin corners that did not permit of the drivers obtaining the remotest idea of what was in front. Marvelous to relate, a large percentage of the cars succeeded in getting through without stopping the road wheels. Some of the drivers of the small and moderate powered cars in Classes A, B, C and D would have been better satisfied with a real timed climb where they would have had a chance of resting for a period before their turn arrived. Bottom gear work was in order most of the day, with 20 per cent, ascents of no great length coming so frequently as to give no opportunity for the water to cool off in the radiator, involving fourteen of the cars in penalties for stops to refill with water. Going down was worse than going up, and the wise regulation giving competitors five minutes each morning to adjust the brakes was here proved to be essential.

Running down the last hill at only I

VIEW OF START OF GRUINARD HILL CLIMB.

TEN HORSE POWER HUMBER GOING UP GRUINARD HILL.

mile from the finishing point of the day's journey came the climax, in the form of a surprise brake test. The cars were stopped at the top, the general impression being that some bad accident had occurred to occasion the break in the run. The cars were then sent down one by one at long intervals, and when well out of sight of those at the summit an official suddenly rushed out of his hiding place and waved a red flag vigorously as a signal for an immediate stoppage. Those who pulled up short within a certain number of yards were then permitted to go ahead; others who ran beyond the predetermined spot had to take the official on board and comply with his directions to suddenly apply the pedal and side lever brakes separately and in unison. The four failures in this surprise brake test were heavily penalized, although loss of marks in this respect would not affect any non-stop award. Of the sixty-one cars still left in the contest, thirtyeight were distinguished with a clean

### SATURDAY, JUNE 19.

This was the shortest journey of the week, 134 miles, the distance being purposely cut down to enable competitors and officials to reach the finish early enough on Saturday afternoon to enable those who so wished to catch the southward bound train for London, as no main line railways run any through service from Scotland on Sundays.

The 14 horse power Argyll met defeat when only 13 miles were wanting to complete the 1,007 miles of the trip. While traveling along a well surfaced level road one of the connecting rods broke—desperate hard luck, as the car had come right through without a single stoppage of the wheels, without a single mechanical trouble, with-

out a puncture, and had put up good times on the hills. To add to the annoyance, the car was practically within sight of the factory where it was built. Two other breakdowns necessitating withdrawal were the 14 horse power Gregoire, with a broken inlet valve (this car was in trouble on every day of the week through overheating caused by a stone striking the radiator on the first day), and the 15 horse power S. P. A., with broken differential gear. A timed hill climb up Fintry Hill, not far from Glasgow, was more in the nature of a speed run, as, although the hill is 2,300 yards in length, the average gradient is only 7 per cent.

#### SUMMARY.

Summarizing the results of the trials, the following figures ought to prove interesting:

The starters numbered sixty-five, and of these fifty-eight were timed in at the finish, giving the splendid percentage of 89.2, a record of finishers for any reliability trial ever held in Great Britain. None of the cars in Classes A and B obtained non-stops for the six days, they being penalizel mainly through overheating on the long hills, and consequently requiring frequent filling up with water and dropping passengers on the hills. But in some cases the records were spoiled for trivial incidents that are entirely beyond the control of any manufacturer. For instance, in Class A, the 10 horse power Riley climbed every hill on the route, including Amulree, without dismounting the passengers; running down hill on the first day with throttle closed to save gasoline, the engine did not pick up at once when the clutch was let in at the bottom, and the car had to be stopped for ten seconds while the engine was cranked over. In Class B the 10 horse power Cadillac had a thirty seconds stop on the first day to relieve an air lock in the gasoline pipe, a ten minutes stop on the fifth day to replace a broken commutator spring, and was further penalized for exceeding sixty minutes in tire repairs on the third day. Seven punctures occurred within a very few miles, all from horseshoe nails, and the Cadillac was the only vehicle to exceed the sixty minutes allowance for tire troubles. This is another case where luck comes in, because this machine bears a fine reputation in England for being particularly economical in respect to tires. In Class B, the 12 horse power Riley also tackled every hill without effort, had no mechanical troubles and but one tire stop of four minutes, yet lost the coveted non-stop certificate through

FIFTY HORSE POWER ARIEL APPROACHING CAIRN O' MOUNT ON FIRST DAY.

cing a cracked spark plug on the first that occupied two minutes. So far as ds the stoppages in the bigger classes,

for the expensive vehicles, the rity were due to badly designed radiathat did not contain sufficient water; ty-one cars suffered penalties for this n alone, quite apart from mechaniroubles, which in the main were quite capable of being put right by adent and without actual repair.

e following obtained non-stop awards he six days:

as C-10-12 h. p. Humber, 14-16 h. p. Miesse. ss D-15 h. p. Mass, 20-30 h. p. Cadillac, p. Straker, 16 h. p. Argyll, 15 h. p. Star, Singer.

ss E-20 h. p. Bell, 20 h. p. Vauxhall, 16 Humber, 20 h. p. Lancia, 15 h. p. Rover, 12 Talbot.

a quarter of an inch thick, and there no bosses where the holes for the g rod were drilled, these holes soon oval, being nearly one-quarter of an arger than the rod on their longest sion. This not only made the gears adly, but allowed a good deal of oil

\*\*ouble was remedied by making two from hard brass rod. The holes ase were filed round, so as to be a over the small diameter of the The bushings were secured by g, as shown in the sketrch. The dotted show the original shape of the small the bushing, which was countersunk ke riveting easier. The holes for the

ON THE ROAD TO TOMINTUI-FOURTH DAY.

rod were originally a little loose, and the parts went together with very little scraping. The fits were found to be good enough so that the leakage of oil was not objectionable.

### New Sliding Valve Engines.

The enormous amount of free advertising which the sliding sleeve type of internal combustion motor has received in England through its adoption by the Daimler Motor Company, of that country, has turned the attention of British inventors to this type of engine, and novel designs are beginning to make their appearance in the patent records. One of these is an engine invented by P. Riley, of Hollybank, Radford road, Coventry. It will be remembered that when the Knight engine was described in a paper read before the Royal A. C. the chief objection urged against it was that there would be a tendency for the sliding sleeves to run hot, and it would, on this account, be difficult to effectively lubricate them. It was evidently this supposed difficulty that Mr. Riley sought to overcome in the design shown by his patent. In order to prevent overheating of the sliding sleeves the latter are not placed between the piston and the water jacketed cylinder, as in the Knight motor, but between concentric water jacketed cylinders. The piston is surrounded by a double walled or jacketed cylinder. the outer wall of which is provided with ring grooves and packing rings, the same as the piston; the outside of this jacketed cylinder is turned down to a smooth finish, and this cylinder is surrounded by the two sliding sleeves, which are similar in every respect to those of the Knight engine. Then comes another water jacketed cylinder which surrounds the sliding sleeves.

The recent tests of the Daimler-Knight engines by the Royal A. C. would seem to indicate that the supposed danger of running the sliding sleeves hot does not exist. The construction above described would add very materially to the weight and bulk of the engine, as well as to the cost of construction.

### Eisenhuth Horseless Vehicle Business to Be Wound Up.

George T. Schull, trustee of the estate of the Eisenhuth Horseless Vehicle Company, of Middletown, Conn., has filed a petition asking for authority to sell at private sale the office furniture and office fixtures of the company, which were not sold at the time the greater portion of the estate of the bankrupt was sold at public auction. The petition will be heard before Gustav B. Carlson, referee in bankruptcy, at his office in Middletown, Conn., on July 10, 1909, at 10 o'clock a. m.

Mr. Schull also proposes to sell all the accounts and choses in action of said estate that still remain uncollected, at public auction, at the former office of the bankrupt in Middletown, Conn., on July 10, 1909, at 2 o'clock in the afternoon.

The delay in the settlement of the estate is said to be due to the pendency of certain actions at law in the Superior Court for Middlesex County. The prospects are that these cases will be determined in October next, or soon thereafter, and as soon as this is done the trustee will proceed to close the matter in bankruptcy.

So far all priority claims, with the exception of one or two minor matters that are in dispute, have been paid. The dividend that will be eventually declared on general claims will not exceed I per cent.

# NEW VEHICLES AND PARTS > >

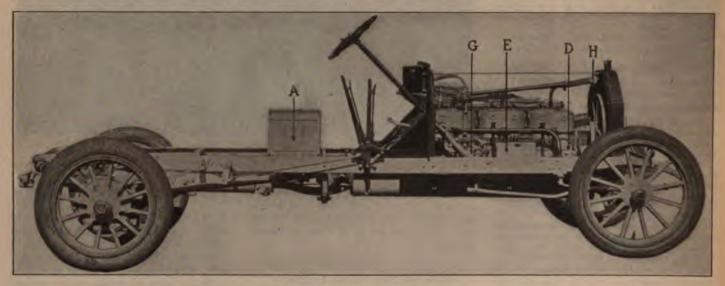

Stevens-Duryea 1910 Models.

Since the Stevens-Duryea Company, of Chicopee Falls, Mass., adopted the power unit, three point support construction in 1904 the cars turned out by it have always been of distinctive design. This construction, whereby the motor crank case, the multiple disc clutch and the sliding pinion change gear are combined in a single unit,

40 horse power, the motor having a bore of 43/4 inches and a stroke of 43/4 inches. Among the chief features of this model are platform spring suspension at the rear, a wheel base of 142 inches and 36x4 inch and 36x5 inch rear wheels. The Model X is a four cylinder, five passenger touring car of 24 horse power, the motor having a bore of 43/4 inches and a stroke of 43/2 inches. This model is practically the same as last year, the changes consisting in a refinement of the body, a slight change in the guard over the rear wheels and the addition of a torsion rod

ing car, fitted with either a runabout body with single bucket seat or with a baby tonneau body. The rear seats of the baby tonneau are easily detached, but are not interchangeable with the single bucket seat of the runabout. The wheel base of the Model XXX is 109 inches, and its frame is supported on semi-elliptic springs, the front ones being 36 inches long and the rear ones 56 inches. This model is equipped with 36x4 inch rear and 36x3½ inch front wheels for the runabout, and 36x4 inch front and rear wheels for the baby tonneau body. It will be noted that only one size

SIDE ELEVATION OF CHASSIS.

A, gasoline tank; D, circulating pump; E, lubricator; G, steering gear housing; H, union joint to radiator.

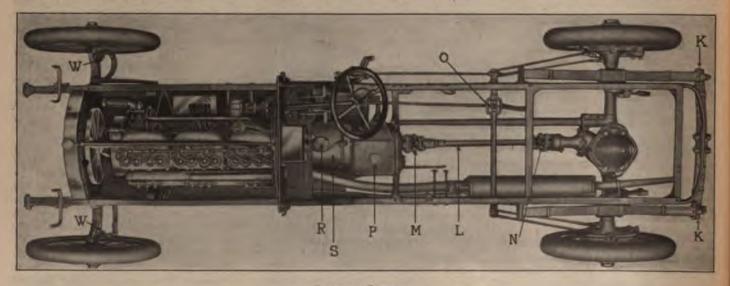

has been retained up to the present, and is embodied in the 1910 models of the company. In 1905 the company began to manufacture six cylinder cars, and its 1910 line also includes one model of this type.

The 1910 line includes three chassis models which may be fitted with different types of bodies. The Model Y is a six cylinder, seven passenger touring car of

to the rear axle. This model also has rear platform springs. Its wheel base is 142 inches, and it is equipped with 34x4 inch wheels both front and rear. Both the Model Y and the Model X may also be fitted with enclosed bodies, and the frame is of such design that touring bodies may be interchanged with limousine or landaulet bodies. Model XXX consists of almost the same chassis as the Model X tour-

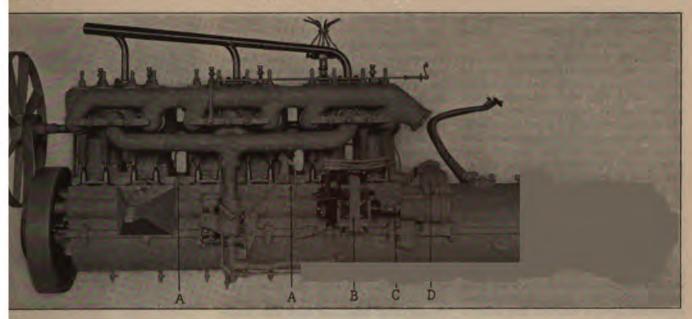

of cylinder is being used for all three models.

It will be seen from the illustrations that the cylinders are cast in pairs and have all valves on one side. Contrary to the usual practice, the cam shaft gears are located at the rear end of the motor and the flywheel at the forward end. The cam shaft gears have a fibre gear crown which insures noiseless operation. These gears

not lubricated. At the left hand side ne crank case there are two studs contact with the upper half of the cam shaft bearings, thus making it ble to adjust these bearings without g the motor apart. The cylinders are nd on special machines, and water is hrough the jackets while the grinding ring place. In this way, it is claimed, rinding wheels may be rotated at their mum speed without danger of overng the metal and thus distorting the ler bore. The manifolds are so ard that the carburetor and inlet manian be removed together without taking xhaust manifold down. The high tenmagneto, which is located on the left side of the motor, is driven direct a gear in the clutch case by means mall universal coupling which obviates rain on the armature shaft. The magis located a considerable distance back e radiator, where it is unusually well ted against water and mud drawn gh the openings of the radiator. It ured to its base by means of a metal and can be removed after loosening inding screw.

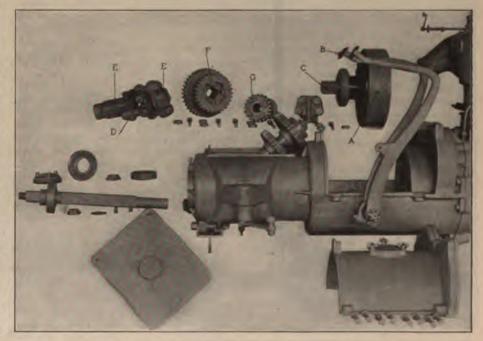

timer, oiler and circulating pump are d on the right hand side of the motor. timer is located at the upper end of tical shaft which is operated from a shaft running parallel with the cam on the opposite side, by means of a gear. The same lay shaft also drives ler and centrifugal pump. The crank is provided with four "breather pipes" gh which the crank chambers may be ly filled with oil. The mechanical forces oil under pressure direct to the crank shaft bearings. This sysf direct lubrication has been found to ost economical of oil, and also to the greatest life of the bearings. The s, connecting rod bearings and other al working parts are lubricated by

splash, the supply of oil in the crank case being constantly replenished by the oil working through the main crank bearings. Into the bottom of the crank case are screwed six standpipes of a certain length, with pet cocks at their lower ends, by means of which any excess of oil in the crank chambers may be drained off.

The crank shaft is forged from special nickel steel, has all bearings ground, and is accurately balanced. The shaft is supported in four large bearings from the upper half of the crank case, which permits of removing the lower half without disturbing the bearing adjustment. A time saving feature of the design is the possibility of

removing any of the pistons without taking the cylinders off. After the lower half of the crank case is removed and the cap on the connecting rod taken off, the connecting rod and piston may be pulled out together. This feature is thought to be a very valuable one, as it is unnecessary to break water connections, remove the cylinders or disturb any of the adjustments when a piston has to be removed. The pistons and connecting rods are carefully equalized in weight so as to insure perfect balance.

The fan is supported from the motor base by means of a forged arm, and rotates on ball bearings. It is driven by

CLUTCH AND TRANSMISSION REMOVED.

A, driving member of clutch; B, clutch pedal; C, driven member of clutch; D, grease cup; E E, squared hubs of universal joint; F, internal teeth of sliding gear to secure direct drive; G, sidewardly projecting teeth on driving pinion to mesh with teeth F.

means of a belt, the tension of which is maintained constant by means of a spring on the supporting arm.

The clutch is of the multiple disc type and operates without lubrication; it is of the same design that has been used since 1904. The driving discs are faced with a friction material composed of woven wire and asbestos, which is claimed to be indestructible, and these discs alternate with driven steel discs, the two sets of discs being pressed together by means of springs. The clutch is disengaged in the usual way by a forward motion of the clutch pedal. The clutch shaft is connected with the change speed gear by means of a square clamp which, unlike universal joints, needs no lubrication.

The change speed gear is of the sliding pinion type, and gives three forward speeds and one reverse. The gears are cut from chrome nickel steel. One of the pinions of the sliding set is cut with four internal teeth, which mesh with four corresponding projections on the end of the driving gear, whereby the direct drive of the third or high speed is obtained. This design of direct drive is said to insure a very compact gear set, to obviate stripping of gears and to insure a positive and quiet change from the second to the high gear without the necessity of first adjusting the motor speed to the car speed. The main driving square shaft and the countershaft of the gear set are carried in annular ball bearings. The entire gear set operates in a bath of oil. To the rear end of the change gear shaft is secured a universal joint by means of a square connection. The rear end of this joint has a long square hole to form a sliding joint with the propeller shaft. This

9 8 9

REAR AXLE DIFFERENTIAL REMOVED.

8, bevel gear; 9, 9 lock collars for adjusting mesh of bevel pinion and gear; 10, 10, clamps for locking adjustment; 11, 12, wing nuts for hand adjustment of brakes; 14, torsion rod.

joint is lubricated by means of a grease cup.

The change gear can be readily inspected or removed by unscrewing three thumbnuts and taking off the cover on the casing, without the removal of the body or the gasoline tank. The inspection cover over the clutch can be taken off by removing the footboards of the front seats.

The rear axle is of the full floating type and embodies a number of exclusive features. One of these is that the driving bevel pinion is forged integral with its shaft. The universal joint near the rear axle is secured to the two shafts it connects by means of squared joints. The housing of the differential is dovetailed with a cover, as shown in the illustration. The differential gears are broached with square holes into which fit the inner square ends of the rear axle shafts. All gears of the rear axle drive are of special chrome nickel steel. The outer ends of the rear axle shafts are also square and have dovetailed flanges pinned to them. Square ioints are used almost exclusively throughout the drive. The advantage of the integral construction of the bevel pinion and its shaft resides not only in the impossibility of the pinion coming loose on its shaft, but also in the fact that if at any time a section needs to be removed, it is sure to be in line and run true upon being replaced.

The differential rotates as a unit on special ball bearings of the cone and cup type, which type is equally efficient under radial and thrust loads. By turning lock collars on the differential case the bevel pinion and its gear may be brought into perfect mesh. Upon removing the two

clamps shown in the illustration of the rear axle it is possible to withdraw the two rear axle shafts and remove the differential gear as a unit.

The rear wheels revolve on the stationary axle housing, and are fitted with annular ball bearings at both ends of the hubs. The pinion shaft is also carried in two annular ball bearings, the two bearings being at a considerable distance apart, so as to relieve all annular strain on the shaft and pinion. The foot brakes, which act on the rear wheel drums, may be readily adjusted by hand by means of wing nuts. One-

STEERING ARM AND WORM WHEEL SECTOR.

half turn is usually sufficient, and the nuts then automatically lock in slots on the upper half of the brake shoe. These brakes are equalized by means of a ball and socket device. The rear axle housing is provided with a tubular torsion rod connecting by a ball and socket spring connection to the cross member of the frame at the rear end of the power unit. The spring seats are free to turn on the rear axle housing, the bearings of the seats being lubricated, whereby all torsional stresses on the springs are obviated.

The sleeves for the spring seat are adjustable lengthwise on the axle housing, so as to make it possible to bring the rear bearing in the gear case in exact alignment with the forward bearing of the rear axle pinion shaft.

The gasoline tank, which is located on the front seat, has a capacity of 22 gallons, and contains an auxiliary supply of 3 gallons. All of the motor accessories are unusually accessibly located. The water leads are connected to the radiator by means of threaded unions, which permit of easily breaking the connections. The steering gear is of the worm and sector type. The worm gear is forged integral with the shaft, and meshes with a worm sector to which the steering arm is connected by a squared, tapered joint. Any wear in the steering gear may be taken up by means of an eccentric bushing. The tie rod of the steering gear is located back of the axle. Incorporated in the construction of the steering knuckle arms are two adjustable stops which prevent the front tires from coming in contact with the frame, and also prevent the possibility of the front wheels becoming locked when turned to the extreme in either direction. The steering rod extending from the bottom of the steering post to the right hand steering knuckle is provided with spring connections to take up any strains. At the upper end of the steering post, above the steering wheel is a stationary quadrant over which the spark lever and throttle lever move.

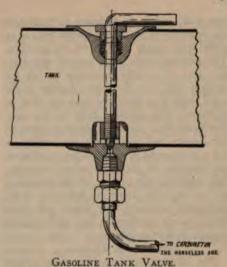

### THE HORSELESS AGE.

are considerably strengthened. The forward end of the rear side springs is connected by offset forgings to the side frames.

### Corbin 1910 Models.

The Corbin Motor Vehicle Corporation, of New Britain, Conn., are preparing to build cars of four different types for the coming season, as follows: Model K touring car, five passengers; Model O roadster, with detachable seats, two, three or four passengers; Model O baby tonneau, four passengers; No. 14, limousine, town car or landaulet, seven passengers.

With the exception of the rake of the steering column, strength of springs and the rear axle gear ratio, the chasses of the different models are similar, except that the wheel base of the No. 14 chassis is 6 inches longer than that of Models K and O. There is little difference between 1909 and 1910 models, most of the changes being in the engine. The latter is supported by the pan in the same manner as formerly, but instead of the deep section aluminum beam, extending across the front of the engine and join-

The Bosch magneto is driven by an aluminum gear on the cam shaft which meshes with an all fibre gear on the magneto shaft.

The rear axle, which is of the semi-floating type, is provided with an axial adjustment for the differential unit, as well as a similar adjustment for the driving pinion.

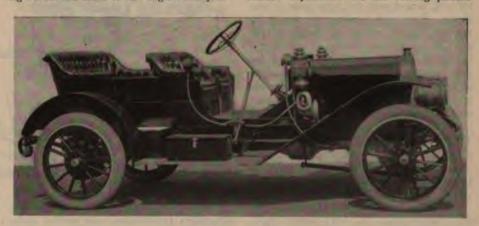

The former is located on top of the quadrant and the latter below.

There is also a foot accelerator on the footboard. A muffler cut-out valve is located

in the exhaust pipe directly in front of the muffler. The gear shifting lever operates in a "self finding" quadrant, permitting of quickly and positively making gear changes. A feature of the emergency brakes, which, like the service brakes, act on the rear hub drums, is that the connection from the hand lever to the brakes is made by rods direct. These brakes are applied by a forward motion of the brake lever,

The steel employed in the springs of this year's Stevens-Duryea cars is said to be of a special grade selected after very exhaustive tests. The rear springs are of the platform type and are provided with connecting shackles specially designed to overcome the side roll on curves of large fast cars. Both the front and the rear spring clips are of special design, which allows of the springs being made without the usual binding holt in the centre, whereby the springs

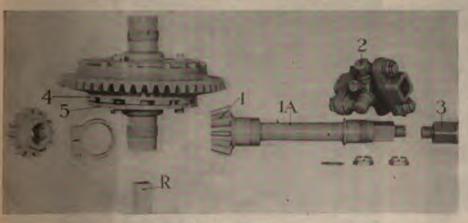

CORBIN 1910 MODEL,

ing the side members of the frame, a lighter section steel beam is used, for the purpose of transmitting the torque reaction of the motor. The timing gears in the new models are enclosed, and the oil pump is now of the vane type and is located at the lower end of the vertical timer shaft, which is driven by helical gears from the cam shaft.

The side members of the frame are t inch deeper at the middle portion than last year. and also deeper at the forward end. This change has improved the looks of the car to a great extent. The flaring pointed fenders, characteristic of the former runabout model, have been discarded in favor of the conventional flat type. The dash is now a separate unit, mounted on a well braced metal frame, as shown. Beneath the slanting footboard there is an oil tank fitted with a cast, oval shaped filling attachment, the opening of which is closed by a hinged cover fitted with a spring. Upon the front of the dash there is a four unit Connecticut coil with a kick switch. The cables enter the coil box from the dash side, instead of from the bottom, as formerly. A rubber gasket is placed between the coil box and the dash. A three lead sight feed oiler is also mounted on the dash, and the bearing through which the steering column passes is split at one side so as to be adjustable for wear by means of a bolt and nut.

As shown by the illustration, this valve, which is of the needle or crush seat type, is combined with the outlet from the gaso-

PARTS OF REAR AXLE DRIVE.

1, bevel pinion; 1A, pinion shaft; 2, rear universal joint; 3, rear end of propeller shaft; 4, differential casing; 3, differential casing cover; R, inner end of one rear axle shaft.

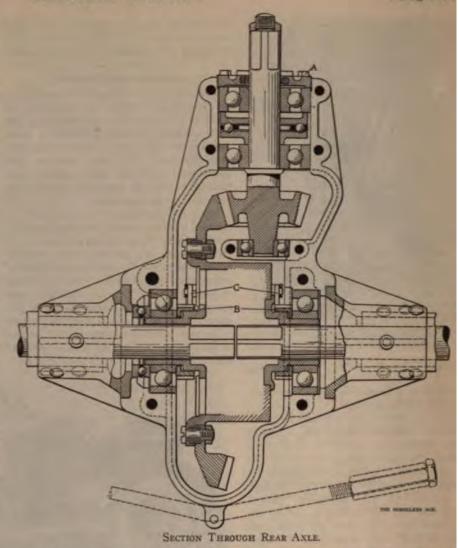

line tank, and is so designed as to obviate the necessity of reaching beneath the car or under the bonnet to shut off the gasoline. The gasoline tank being beneath the driver's seat, it is only necessary to lift the cushion and turn the valve handle to the right until it is seated to stop the flow of gasoline. The gasoline tank on the runabout and baby tonneau models is arranged for gravity feed under ordinary conditions. but a hand pump is provided for creating an air pressure in the tank when necessary, thus necessitating a valve which will admit air to the tank under the influence of atmospheric pressure, and which will close when the air pressure in the tank becomes greater than atmospheric.

### REAR AXLE HOUSING.

The illustration shows the arrangement of the driving pinion, which is integral with the shaft and is supported by three annular bearings and provided with a thrust bearing which may be adjusted by the crown nut A, which is locked by a pawl, not shown. The method of driving the differential housing by means of thimbles which register with it and with the large gear is also shown. This unit is adjustable axially by the cup nuts B, which are locked by the pawls C. A feature worthy of special notice is an opening in the top half of the axle housing, facilitating the introduction of lubricant to the housing. The opening, which is oval in shape, is closed by a cover secured by two wing nuts. The standard rear axle gear ratios are: For touring cars, 31/2 to 1; roadster, 31/4 to 1; baby tonneau, 31/2 to 1, and the seven passenger car, 4 to 1.

### Interlaced Curled Hair Fabric for Automobile Cushions.

The American Sanitary Mattress Company, Philadelphia, Pa., have placed upon

the market an interlaced curled hair fabric for automobile cushions for which several advantages are claimed over stuffed cush-

ions. The interlacing process is claimed make the stuffing one piece, thereby redering it springy. The fabric is made

FRONT VIEW OF MOTOR

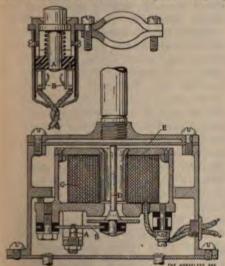

FORWARD PART OF CHASSIS.

one block in any desired thickness, from 1 inch to 8 inches, either loosely or tightly interlaced. The fabric is entirely independent of the covering, and is so made as to insure thorough ventilation. The surface is smooth, no tuftings being used.

### Holtzer-Cabot Electric Horn and Hand Wheel Switch.

The Holtzer-Cabot Electric Company, of Boston, Mass., have placed an electrically operated signal horn on the market which is similar to other electric horns in principle, but different in construction. As in other horns, the sound is produced by causing a diaphragm to vibrate under the action of a clapper or hammer which generally strikes the centre of the diaphragm, usually of metal, hard rubber, celluloid or wood. However, in this instrument the clapper strikes the diaphragm twice each time the armature to which it is attached is attracted by its electro-magnet; that is,

HOLTZER-CABOT ELECTRIC HORN AND HAND WHEEL SWITCH.

once when the armature is drawn toward the magnet and again when it is released.

The construction is shown by the cut. When the circuit, comprising a 6 volt source of direct current, is closed, the current will flow through the contact point A secured to the spring blade B, and thus energize the magnet coil which will attract the armature attached to but insulated from the spring blade. The clapper D is, therefore, caused to strike the sheet bronze diaphragm E and deflect it so that the end of D leaves E, and on the return stroke, prior to again completing the circuit at A, it again strikes E, because of the action of the spring blade B.

The mechanism is enclosed in a polished cast bronze case 3½ inches in diameter and 2¾ inches high. Three holes are provided in the bottom plate for screws to secure it to the car. The wires which conduct current to the magnet coil pass through a hard rubber bushing in the side of the case, and the bell-shaped portion of the horn is attached to the upper plate, as shown.

For closing the circuit to operate the horn, a push button switch attached to a length of flexible conductor is furnished. The switch may be readily clamped to a spoke of the hand wheel or other convenient part which will fit the clamp.

The switch consists of a tubular brass casing about seven-eighths of an inch in diameter and 2 inches long, which has an interior insulating wall of sheet fibre and is secured to the upper part of the switch by two small round headed screws. The push button is made of hard rubber and has a disc of mother-of-pearl inserted in the top surface to decorate it. A square brass plunger A, rounded at the end, is attached to the button, which when depressed against the force of the coiled spring shown causes A to make contact with the stamped bronze pieces B, which are secured to the binding posts to which the conducting cable is connected.

### Rogers' Cleansing and Polishing Preparations.

The Detroit Varnish Company, of Detroit, Mich., are bringing out a line of cleansing and polishing preparations for use on automobiles. These preparations are sold under the name of Rogers' automobile specialties, and include the foling: Carbon solvent, for cleaning the interior of engine cylinders; Auto-brite, for polishing and preserving varnished surfaces; Brass-shine, for polishing metal parts; Auto-top dressing, for redressing tops, lamp hoods and tire covers; Klenzer, for cleaning varnished and painted surfaces. The name Rogers is prefixed to all the above titles. These specialties are distributed by the Automobile Equipment Company, 260 Jefferson avenue, Detroit, Mich.

### Stamped Aluminum Floor Covering.

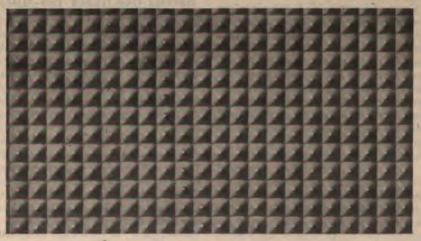

The Factory Sales Corporation, 1438 Michigan avenue, Chicago, have just brought out a new floor covering for automobiles, designed to supersede rubber,

corkaline and the various covers heretofore used. It is stamped from sheet aluminum alloy in pyramid form, and after
stamping is sand blasted to give it all the
appearance of the cast aluminum floors
found in some of the most finely finished
cars. It is designed to lay over the regular
floor boards, securing it in place by the use
of a special binding strip provided for the
purpose.

The metal is claimed to be much harder than the ordinary aluminum, making it very durable. The prime advantage of the covering is its cleanliness, which will appeal to everyone using the car. It is furnished in sheets 36 inches wide by 85 inches in length. Being finished clear to the edges, there is no waste.

### The Union Dry Cell.

The Union Battery Company, of Belleville, N. J., have recently placed on the market a dry cell intended for ignition work which is enclosed in a 21/2 inch square cardboard box 6 inches high. This cell is known as No. 6, and is at present the only size manufactured by the company put up in this manner, but in the near future larger cells will be placed on the market. The top of the box fits the binding posts and prevents the cell from turning, and the square package permits the cells to be conveniently packed in the battery box without the use of filling materials, such as waste, usually found necessary to prevent the cells from rattling. The manufacturers have conducted numerous tests on these cells. They inform us that in one test, where a battery was connected to a coil taking one-quarter of an ampere, it operated the coil for a continuous period of 114 hours, and at the end of this time showed a current on short circuit of 21/2 amperes. One of the claims made for the cell is that because of its high internal resistance it cannot be damaged by an excessive flow of current on short circuit, and it therefore recuperates rapidly after having been worked to the

PYRAMIDE ALUMINUM FLOOR COVERING

### A Ceiling Suspended Drill Press.

Birch & Birch, of Crawfordsville, Ind., have brought out a high speed drill press which may be used for work which cannot be handled by the ordinary floor mounted machine. The tubular column is adjustable to the height of the work, and the machine may be used to drill at the centre of any diameter by removing the table and the lower column to which it is secured. The spindle head is fastened to one end of the upper column, which is clamped into the stationary sleeve of the drive pulley bracket. The lower column is similarly clamped into the spindle head. The table is clamped on the lower column, and all clamping screws are provided with swinging levers to avoid the necessity of a wrench. The drill spindle has lever feed and is driven by a three step pulley, and the machine may be furnished with counterweights to balance the weight of the head and column, and by using longer or shorter connecting tubes from the stationary drive pulley bracket to the ceiling flange the machine may be adapted to any height of ceiling.

### Grout Company Reorganized.

The Grout Automobile Company, of Orange, Mass., which has been in the hands of a receiver for a number of years, has been reorganized with Walter J. Gould as president, Elisha S. Hall treasurer and Geo. E. Dexter secretary. Mr. Gould has been connected with the Grout Company for a number of years as salesman and demonstrator. Mr. Hall is treasurer of the Orange Co-operatve Savings Bank, and Mr. Dexter secretary of the Chase Turbine Company. The new company plans to continue the manufacture of the present Grout models, and to increase the manufacturing facilities so as to be in position to do a good business during the 1910 season. The disposal of the property to the new company will remove the principal obstacle to a settlement of the estate. of the late William L. Grout.

# Dividend for Electric Vehicle Company Creditors.

Judge Cross, of the United States Circuit Court of Trenton, N. J., has signed an order authorizing the receivers for the Electric Vehicle Company to pay all holders of proved unsecured claims a dividend of 20 per cent. The order permits the receivers to accept and pay the same dividend on claims aggregating \$101,094.35, which had been filed out of time, and bars all creditors who have not heretofore presented their claims from participating in the proposed distribution.

The petition pursuant to which the order was made recites that unsecured claims to the amount of \$3,282,557.42, exclusive of interest, have been presented. Of this amount claims aggregating \$2,710,235.49 were allowed in full, to which is to be added the \$101,094.35 allowed by the order just signed, while claims aggregating

\$18,409.33 were allowed for amounts totaling \$11,350.27.

The petition recites that the receivers have \$150,000 cash in hand, and will receive \$430,000 from a reorganization of the committee for the assets of the company, pursuant to an order of court made June 15.

The order signed by Judge Cross extends the time of filing of the receivers' final report sixty days from July 1.

# Convention of Packard Repair Shop Superintendents.

Superintendents of the mechanical departments of Packard agencies throughout the country visited the factory of the Packard Motor Car Company at Detroit during the past two weeks. Meetings were held daily at which the mechanical features of the 1910 models were discussed, as well as the general conduct of repair work and shop service. The visitors also spent much time in the factory and took drives in the new cars. Most of the men are graduates of the Packard factory. Their own experience during the course of the year naturally proved most interesting to the factory experts, and so the conference was mutually beneficial. These meetings will be held annually hereafter.

# Outgrowth of the Transient Garage Business.

A fight is being made at Poughkeepsie, N. Y., against the boy runners of local garages, who are said to "hang around" the best hotels of the city, and as soon as an automobile arrives urge the driver to put it up at the particular garage they represent. The objection to these runners is said to be based upon the fact that when they are not engaged in actual service they appear to be engaged in active deviltry. The garage owners pay them 25 cents for every car that they bring to their premises. It is thought that the only method of putting these runners out of business is to have an ordinance passed which bars their occupation.

# Buffalo One Gallon Ton-Mileage Contest.

Fuel economy contests seem to be gaining in popularity, as the large Buffalo A. C. has just decided to organize an event of this kind. We believe, by the way, that this is the first competitive event ever conducted by this club, which, next to the A. C. A., is the largest organization of its kind in the country. The event planned will be a I gallon mileage contest, and will be in charge of a committee headed by Laurens Enos. There will be five classes, as follows: Class A, for cars selling up to \$1,000; Class B, cars from \$1,001 to \$2000; Class C, cars from \$2,001 to \$3,000; Class D, cars from \$3,001 to \$4,000; Class E, cars above \$4,000. In each class there will be two divisions, one for private owners and one for manufacturers and dealers. At the start of the contest each car will be weighed and furnished with I gallon of gasoline, and the car which produces the greatest number of ton-miles with this amount of fuel will be the winner. There will be one winner in each division, and also a general winner of the contest. The event is scheduled for Wednesday, July 7.

### Garage Lighting and Ventilating.

It is not usual to have the car storage space as brightly lighted as the repair shop or the office, and usually the light admitted by the windows at one end of the space is sufficient for the requirements. However, it is advisable to provide a fitting for attaching a connection for a hand lamp or a portable buffer for polishing the bright work on the car, to the wall at the back of each car, or perhaps each two cars. The repair shop should be lighted preferably by skylights, so arranged as not to admit direct sunlight. The office and showrooms should always be brightly lighted, and they usually have plate glass show windows.

Electric lighting systems of various kinds are at present used in garages, and include incandescent globes arranged singly or in clusters and suspended from the ceiling or from the walls and pillars of the building, or a system using enclosed are lamps. Nernst lamps or mercury vapor lamps suspended overhead. The latter systems are more economical, and for lighting the car storage space they are ideal, provided receptacles are arranged so that plugs attached to portable incandescent lamps may be connected for local lighting when examining or working on the car. The runway leading into a garage should not be brightly illuminated, because the contrast between it and the dimly lighted street may be so great as to momentarily blind a driver. A good arrangement consists of a lamp of not over 100 candle power on either side of the doorway on the outside, and a row of incandescent lamps fitted with reflectors to throw the light toward the ceiling and arranged above the door in the driveway. This arrangement is particularly pleasing and viewing the doorway from the street side gives an impression of much greater brightness than really exists, because the light is evenly distributed and there are no deep shadows and very bright spaces, such as there would be if the light was thrown directly down, instead of being reflected to the ceiling, which should be painted white.

At the recent convention of the German Association of fire department heads in Hamburg, Chief Reichel, of the Berlin department, reported that thirty-one fire departments in Germany have seventy-one motor fire wagons in service at the present time. In the course of the convention the new motor propelled "fire train" of the Hamburg department was inspected by the delegates.

# COMMUNICATIONS

# Stopping When the Brakes Fail. Editor Horseless Age:

I am very much interested in the recent discussion in your columns of the best way to handle a car that stalls ascending a hill. Mr. Moore's plan is clear if the engine is simply stalled, but I doubt if it would work in practice, for while making the shifts the car would gain too much momentum to stop it.

Your suggestion to use the low gear with the clutch in is the only help possible if the brakes are doing nothing, but the assumption is that the brakes would be at least retarding some, and it would be unwise to throw them off and run the chance of catching the low gear. If the low gear was already engaged the plan might work all right. On one occasion, up a steep and winding hill which my car would usually take easily on the second, the engine rather suddenly lost power, on account, probably, of overheating, and having no momentum the car stopped and commenced to back before I could engage the low gear. I could, perhaps, have kept at it and caught the low, but thought it better to use the brakes, which have always held, and stop the car before shifting gears. This time the brakes did not hold strongly enough to stop her, and as the speed appeared to slightly increase I played for safety and backed into the bank. Result: almost an upset, but no damage. In all probability I could have caught the low and gone on, or could possibly have stopped by the brakes, or at least steadied enough to back down, but it is a difficult job to steer backward down a steep hill. A failure of either of these plans would have put me in great peril, and I still think I did the wisest thing, as safety is the first consideration.

I would like to ask, Is it possible to engage the low speed ahead when the car has started to move backward, even slowly? The weight of the car through the friction of the rear wheels is turning the shaft and the gears in the reverse direction, and would not this make it impossible to change? Are sprags (once widely advertised) of real, practical value? J.

[Answering your first question, not all cars are fitted with sliding change speed gears, and with almost all other types of change gears it is possible to engage the low gear, no matter what the speed of the car may be, although this may subject parts of the mechanism to great strain. We believe it quite possible to enmesh the gears of the first forward speed of a sliding gear if the car is running backward only slowly. Much, of course, depends upon the amount of chamfering given the tooth ends. If a car has once attained a high speed backward down hill there is little possibility of getting it under control again, and every

effort should be made to prevent it from acquiring this backward speed. If one is not sure of being able to engage the low gear and safely steering down the hill backward at a moderate speed, if there is a bank at one side of the road of sufficient height to promise to hold the car, it is certainly the best plan to steer into the bank. No attempt should be made to turn the car through a quarter circle and run with the two rear wheels squarely against the bank, as there is then considerable danger of overturning the car, but the car should be run against the curb at an angle depending upon the steepness of the grade, the height of the bank and the speed already acquired.

Sprags are efficient safety devices when properly used. They are of no use when let down after the car has already acquired considerable backward speed. If you are not sure of your brakes you should let the sprag down upon starting up a particularly steep hill, or if your engine dies down on the low gear you should let the sprag down before the car comes to a stop.—ED.]

### Oueries.

Editor Horseless Age:

Which would, under the same conditions, wear the longer time, a spur or a bevel gear? How much longer? Which takes the more power? How much more? Which makes the more noise? How much more?

[A spur gear is generally more efficient than a bevel gear, for the reason that the bevel gear cannot be, or at least generally is not, as accurately cut as a spur gear. The bevel gear would, therefore, take more power and have a greater tendency to be noisy, but no actual figures can be given for the differences, as they depend upon the pitch line or tooth velocity, pressure on teeth, size of teeth, material, accuracy of the teeth and other factors. With equal pitch line velocities and equal tooth pressures spur and bevel gears should last about the same length of time.—Ep.]

### Opposed Engine Crank Connection. Editor Horseless Age:

As a subscriber to your paper, I take the liberty to ask the following questions: Kindly explain the method used in a recent four cylinder opposed motor to get the pitman rods working in a straight line. How does this construction compare in efficiency with the usual connecting rod? What are the disadvantages, if any? Do the advantages more than offset the disadvantages? Is it patented?

Brewster Godlove.

[The usual connecting rod is replaced by two eccentrics, one over the other. The two eccentrics have the same throw, and as the centre of the inner one travels away from the centre line of the pistons, the centre of the outer one travels in the opposite direction relative to the inner one and always remains in the centre line of the piston. We do not believe that this arrangement is as efficient mechanically as the regular connecting rod arrangement. Its advantage lies in the fact that it makes a very compact motor. Whether the advantages outweigh the disadvantages is a matter of opinion, for there is no means of direct comparison between mechanical efficiency and compactness. We cannot say whether the construction is patented. You would have to make a search of the patent records.—Ep.]

### Hill Climbing Power Not Proportional to Horse Power.

Editor Horseless Age:

C. DEP. F.

[That the 12 horse power car climbs hills as well as the 18 horse power car may be due to one or more of the following three reasons: The 12 horse power car may be lighter than the 18 horse power car; the 12 horse power car may have more gear changes than the 18 horse power car, permitting you to run on a suitable gear a greater part of the time; the 12 horse power car may be more conservatively rated than the 18 horse power.—Ep.]

### French Motor Plowing Contest.

The committee on agricultural machinery recently appointed by the Automobile Club of France has decided to organize a motor plowing competition in connection with the motor agricultural show at Amiens, July 22 and 23, to which will be attached cash prizes to the amount of 2,000 francs. In making the awards the jury will take into account: (1) The execution of the work; (2) cost of plowing per hectare; (3) time necessary for the transportation, installation and putting into operation; (4) number of men necessary for operating the machine; (5) facility of application under different topographical conditions; (6) possibility of using the motor of the machine for other agricultural purposes. In order to create a basis of comparison between the different motor plows taking part in the competition, all calculations will be based on a depth of 18 centimetres, which will be the minimum depth to which the soil must be turned. All types of mechanically propelled plows of both French and foreign manufacture are eligible for entry in this contest. The entry fee is 50 francs per plow, but one-half of this sum will be returned to the entrants who actually present their plows. The entries closed on June 30.

The city council of Budapest, Hungary, has made an appropriation for the purchase of two automobiles for the service of the police department. It is intended to purchase additional vehicles shortly.

# Commercial Applications.

### The Automobile in Paper Making. By J. E. J.

A letter from Ottawa, Canada, states that the E. B. Eddy Company, which is perhaps the largest wood pulp and paper making concern in the Dominion, now almost entirely uses motor vehicles in the yards, hauling paper, pulp, wood, etc. The displacement of horses by motor trucks is a novelty among paper manufacturers in Canada. The company says that a great saving has been effected, each motor doing the work that was formerly done by two and a half to three teams.

The motor vehicle is used for delivering goods to all local customers, and also for loading and unloading cars near the mill. Superintendent George H. Millen states that formerly it took three men and a team of horses a quarter of a day to deliver a load to the newspaper offices; now the motor truck delivers a load of three tons in half an hour. One truck has been in use four years. It is of Springfield make, and has a capacity of three tons. Another with a capacity of five tons, and a trailer attached, carrying as much more, made in New York, was purchased a year ago. With these vehicles the company does all its local carrying nine months in the year. The snow is too deep in the other three months.

The largest truck of the Eddy Company, which weighs thirty tons, is capable of hauling thirty tons more of freight on a railway track, and is often used for shunting instead of a steam engine. One man accompanies the motor truck in addition to the driver, and these two are able to do the loading and unloading. Though the company has to use horses while the snow is on the ground, they are bought in a dull market and sold when prices rule higher in the spring. Anyway it pays to keep the motor vehicles.

### Reliability of Motor Propelled Fire Wagons.

Captain J. C. Barrett of Engine Company No. 6, of Minneapolis, Minn., at the recent meeting of State firemen in Cloquet read a paper on motor fire apparatus, from which the following extracts illustrative of the dependability of such apparatus are taken:

In the city of Vancouver, during the last year's service, the machines of the central station, an auto hose combination chemical, an auto chemical double 60 gallon and a hose wagon with a carrying capacity of 1,500 feet of 2½ inch hose, answered 382 alarms of fire and covered a distance of 750 miles without any failures to respond to alarms. The cost of maintenance was 60 per cent. less than that of the former horse drawn equipment. When responding to alarms the driver of an auto has

much better control over his machine than the driver of horse drawn apparatus.

The city of Springfield, Mass., has in service two auxiliary squad wagons, and 386 alarms were answered. The autos never failed to start but once, and that failure was due to some malicious person having crossed the terminal wires of the batteries. The machine was delayed three minutes.

The automobile of Chief Canterbury of the Minneapolis fire department was put to a severe test when placed in service July 15, 1908. In ten months' service it answered over 380 alarms, and at no time did it fail to respond to an alarm. Last winter conditions were very unfavorable. Steam railroads and street car lines were unable to operate successfully, owing to heavy snowstorms. At no time did the auto fail to do its work more successfully than the horse. The auto has been demonstrated so satisfactorily to the city officials of Minneapolis that they have purchased a police patrol auto wagon.

The annual fire loss is more than enough to provide the most efficient auto apparatus in every city, village and town in the United States today. Hundreds of fires could have been put out with only a nominal loss if they could have been reached five minutes, and sometimes one minute, sooner. The auto apparatus, manifestly, should not be confined to chemical wagons or auto squads carrying small chemicals.

With the horse drawn apparatus you have drivers who are superfluous men. Drivers have to remain with their horses and take care of them, while with the auto every man is available for fighting purposes. But it is in the smaller cities and towns that cannot afford the cost of a steamer that great additional protection will be givencities ranging from 10,000 down to 500 people. As to economy, suppose a combination chemical and hose wagon, two horses, harness and complete equipment cost \$3,000, which is a moderate estimate; it will probably cost 10 per cent. of this amount to feed and care for the horses for one year, to say nothing of shoeing and repairs. The depreciation in the horse would amount to quite a sum also; while, on the other hand, all you would need would be a barrel of gasoline and a half barrel of engine oil. Twenty miles an hour is ample speed for fire department service. as it is three or four times as fast as the horse will go for any considerable distance, and that is as high a speed as would be maintained in practice in city fire depart-

# Indianapolis Grocers Adopt Motor Delivery.

Within the last year Indianapolis grocers, both wholesale and retail, have found it profitable to do their city delivery work with automobile trucks and delivery wagons. The Court House Grocery Company, probably the largest retail grocery concern in that city, has begun an experi-

ment with automobile delivery, and expects to discard all of its horse drawn equipment if the experiment warrants. Schnull & Co., August M. Kuhn & Co. and W. T. Bacon & Co., wholesale grocery concerns, are now doing their city delivery work with automobiles. J. T. Powers & Sons, the Columbia Grocery Company and N. A. Moore & Co. are other large retail grocery concerns using automobiles in their business.

# Milwaukee Commission Merchants Adopt Motor Trucks.

The motor truck is invading a new field in Milwaukee, Wis., several of the big commission houses on Broadway, known as "Commission Row," and extending about six blocks from the centre of the city to Milwaukee River, having purchased cars of this type for quick delivery and transportation services. Perishable goods, fruits and vegetables constitute the bulk of the business, and it is figured that 25 per cent. of the loss incurred in delivery to distant stores and branches in the city can be saved by employing the motor trucks. E. R. Godfrey & Co., 257-259 Broadway, general commission merchants, placed a truck in service about a year ago and another has now been ordered. Meanwhile several other houses are following the example.

### New Buffalo Taxicab Company.

The Buffalo Taxicab Company have leased the Coliseum Building at 32 Edward street. Besides a large taxicab service the company will rent touring cars. They also expect to conduct a public garage. The new company have taken over the property of the E. R. Thomas Taxicab and Transfer Company, which gives them an equipment of sixteen Thomas cars, ten Ewing taxicabs and five Stearns cars. W. A. Morgan, of Buffalo, is president, S. S. Olds manager and W. B. Ford secretary and treasurer. E. R. Thomas, the well known automobile manufacturer, holds considerable stock in the concern, we learn.

# Autos Cheaper Than Horses in Municipal Service.

Chief Clancy, of the Milwaukee (Wis.) fire department, will recommend to the common council that a runabout, at least, be purchased for every assistant fire chief in Milwaukee. He has been using a touring car for two years, while assistant chiefs, who are distributed over a wide territory, are using horses, two being allotted to each, one for reserve. Last week, however, the chief purchased a number of horses, but was disappointed to find that none could be purchased for less than \$285.

"At this rate, runabouts could be purchased for each assistant chief, and at the end of the year the city would be money ahead," said Mr. Clancy. "Feed is unusually high, and our last consignment of oats cost 60 cents a bushel. Our horses are fed nine quarts a day on the average, but the chiefs' horses need ten to eleven quarts, as they are subjected to harder usage. Each has

two. The difference in the cost of maintenance alone would pay for a runabout in one year's time."

The state of finances of the city of Milwaukee, Wis., forced the common council last week to stop at one purchase of a touring car, while two were demanded, one by the board of public works and another by the council itself. The car will be used jointly by the commissioners of public works and the committees of the council. City Clerk Edwin Hinkel will be "official keeper" and issue requisitions for the use of the car. The machine is a Peerless, and the appropriation amounts to \$4,000.

### Spokane (Wash.) Taxicab Service.

The Spokane Taxicab Company has been organized in Spokane with \$50,000 capital stock by C. E. McBroom, cashier of the Exchange National Bank: Robert H. Cosgrove, secretary of the Spokane Interstate Fair Association, and J. D. Williams, an experienced taxicab man, who is general manager of the corporation. Mr. Williams announces that an order has been placed for ten cabs of the four cylinder type manufactured by the De Dion-Bouton Company. They will be delivered early in August, when a contract will be awarded for ten more. The cost of the first ten is placed at \$27,000, exclusive of freight charges.

During the Interstate Fair in Spokane September 20 to 25 the company intends to maintain a station at the fair grounds, and will run cabs to and from the city every three minutes. The following schedule of rates has been made: For from one to three passengers, 30 cents for the first quarter mile and 10 cents for every quarter mile thereafter. A charge of 10 cents for each minute's wait while the car is chartered. These charges are the same for from three to six passengers, except that 10 cents is charged for one-sixth of a mile after the first quarter.

### Commercial Notes.

Patterson & Holloway, a new agency at Monroe, Wis., have established a livery service, four touring cars comprising the initial equipment.

Alex. Marks has established an automobile service between Pueblo and Rye, Col. He will make three round trips a week—on Tuesdays, Thursdays and Saturdays.

A Mr. Allen, of Colorado City, is planning to establish a motor bus service between Craig and Steamboat Springs, Col., a distance of 50 miles, with two large touring cars.

A motor bus line is to be established between Albany and Schenectady, N. Y., by the Eastern Auto Tourist Company. The first line to be opened will start at State and Eagle streets, Albany, and end at State street, Schenectady. Other lines are in contemplation.

An automobile service is to be established between Ironton and Proctorville, Ohio. as soon as a certain stretch of road at Coalgrove has been repaired by the authorities. S. G. Griffith, of Huntington, Ind., will put on a fourteen passenger bus, which will make two round trips a day.

# Franklin Branch Managers' Meeting.

The traveling salesmen and branch managers of the H. H. Franklin Manufacturing Company recently completed their summer conference at the company's factory in Syracuse, where daily sessions were held for a week. During this period the attendants were instructed in the changes made in Franklin models for 1910. The conference was conducted by Sales Manager F. R. Bump, and the salesmen were addressed by Vice President Giles H. Stillwell, Chief Engineer John Wilkinson, Assistant Engineer Arthur Holmes, Sundry Department Manager J. G. Barker, Comptroller H. B. Webb, Superintendent F. J. Haynes, Traffic Manager Herbert Hess and Engineer W. F. Kneip. Several trips in the new models of the company were made by those in attendance.

### Registrations in California.

According to the report of the Secretary of State of California, 938 motor vehicles were registered in the State during May. In May, 1907, there were 613 registrations; in May, 1908, there were 637. In May, 1909, there were recorded 135 transfers or registrations of machines under the names of new owners. This is the record number of transfers in one month in California. Licenses were issued to 180 chauffeurs. In the first five months of 1909 there were 3,632 registrations, 501 transfers and 974 chauffeurs' licenses. It is probable that the total number of registrations for the year will reach 7,500.

### Test for Acid in Oil.

The following test, which can be made by anyone with simple apparatus, is recommended for detecting acidity of lubricating oil: Procure from the druggist a solution of sodium carbonate in an equal weight of water. Take a small quantity of the oil and an equal amount of the sodium solution. Place them in a bottle, shake, then allow to stand. If there is any acid present it will settle to the bottom as a precipitate, the amount of precipitation indicating the amount of acid present.

### Business Opportunity.

We have an inquiry from a large New England company for the names of manufacturers of gasoline engines who build or are willing to build an engine of about 45 horse power with four opposed horizontal cylinders. The engine is to run at constant speed, preferably 500 r. p. m. The company expect to buy one or more such engines. We shall be glad to forward the addresses of any of our readers who may be in a position to satisfy the wants of our inquirer.

### Rugs for Automobiles.

By J. E. J.

The development of the automobile industry has been of great advantage to other trades and industries, as has been pointed out in The Horseless Age. It has, for instance, been of material benefit to the rubber industry, the manufacture of linoleum, to the upholstery and upholstery hardware trades, metals, oils, etc. A list of the trades benefited would fill a column.

Attention was drawn in THE HORSELESS Age last autumn to the increased use of linoleum as a floor covering for the automobile. Luxury will, however, have none of this material, serviceable as it may be. The high class rug now has the call from the lover of the luxurious. From the beginning the rug and carpet salesmen have observed the effect of the motor vehicle industry on their business, until now special designs and grades of rugs and carpets are made, ousting from the favor of the wealthy the linoleum, straw matting and kindred coverings that have hitherto been used. It was but natural that these serviceable goods should be superseded by the more pleasing, soft and attractive pile rugs,

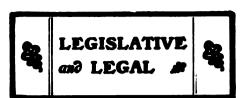

The rugs made to order for motor vehicles are expensive and of superior workmanship, the dyes being of a high grade and not of the aniline order, which are fugitive. The buyer who purchases a rug of pile effect gets a delightfully attractive and comfortable article. The patrons who buy these goods are accustomed to expending large sums on their cars. Some of the enterprising motor rug salesmen have had fitted up for their convenience ingenious representations of the body of an automobile, full size. Sometimes a diagram of a car is made, by means of which the prospective purchaser of a rug can get an idea of sizes and appearance.

Some patrons of the rug merchant require rugs in which is woven a symbol indicative of motoring, or a rug with an inscription. The rugs come in a short nap, or with a long, flowing, worsted-like effect, or with a pile effect.

The chief trouble with these impedimenta—some misname them accessories—is that they gather dirt and mud in greater degree than do linoleum or rubber mats.

The hassock is likewise largely pushed by two houses that devote themselves to the manufacture of this kind of foot rest. These concerns are situated in New York and Chicago, and they claim that their output is of much comfort to riders. The remnants of carpeting are used in the making of these articles.

Fernand Charron has resigned as managing director of the firm of Charron, Ltd., and has been succeeded by Georges Koenigswerther. Charron, it is understood, will enter the Bayard-Clement firm in Levallois, he being a son-in-law of M. Clement. Mr. Charron still retains his financial interest in the firm bearing his name.

### New York City Taxicab Ordinance.

In our issue of June 2 we printed the New York city taxicab ordinance as it was passed by the board of aldermen on June 15. This ordinance was vetoed by the mayor because it did not include a suitable profision for regulating the fares to be charged. It was therefore modified in accordance with the mayor's wishes, and approved by him on June 29. With the exception of the following sections the ordinance as originally adopted by the board of aldermen remains unchanged:

Each vehicle upon which a taximeter is affixed shall be licensed and the owner thereof shall pay annually such fees as are hereinafter provided:

Each special taxicab, \$10. Each public taxicab, \$10.

Each driver of a taxicab shall pay an annual license fee of \$2. The owner or driver of any hack upon which a taximeter is affixed, and who has duly procured a license to use or drive such vehicle according to the provisions of any ordinance hereinbefore enacted, may continue to use or drive said vehicle under such license until its expiration.

The legal maximum rate provided in this ordinance, and any schedule of rates promulgated by the owner of any such vehicle charging less than the legal maximum rate, shall be displayed in a conspicuous place on the inside of such vehicle.

### LEGAL MAXIMUM RATES.

For each taxicab intended to seat two persons inside and driven by motive power, for one-half mile or any part thereof, 30 cents.

For each additional quarter mile or any part thereof, 10 cents.

For waiting time at the rate of \$1 per hour.

For each taxicab intended to seat four persons inside and driven by motive power, for one-half mile or any part thereof, 40 cents.

For each additional quarter mile or part thereof, 10 cents.

For waiting time at the rate of \$1.50 per hour.

For one piece of baggage, 20 cents.

No charge shall be made for handbags, dress suit cases or child under five years of age by any taxicab.

All rates of fare shall depend on the number of persons which each vehicle is intended to seat inside and not on the number of passengers actually carried, and no owner or driver of any taxicab shall use or permit to be used on such vehicle any taximeter which shall calculate or indicate a rate of fare which shall depend on the number of persons actually carried, under a penalty of \$25 for each offense.

# To Stop Abuse of Manufacturers' License Tags.

State Commissioner of Motor Vehicles J. B. R. Smith, of New Jersey, has decided to adopt drastic measures to prevent the increasing abuse of manufacturers' licenses. In a circular sent by Mr. Smith to all holders of such licenses he draws attention to three violations of the law, viz., first, the practice of using only one official identification tag on a car where the law expressly requires two to be carried at all times; second, the practice of loaning license tags, and, third, the use of unofficial markers. Mr. Smith states in the circular that he has instructed his deputies that on and after July I every car found carrying only one official identification marker and every car without a registration certificate shall be immediately taken off the streets, and that upon notification to the department the registration certificate will be summarily revoked; and that on and after July 4 every car carrying a loaned marker will be regarded as driven under a false registration, and the driver thereof will be held for grand jury action.

### Indianapolis Police Chief Indicted.

After a very thorough investigation, in which a score of witnesses were examined, the grand jury has indicted Chief Robert Metzger, Captain Adolph Asch and Sergeant Charles Barmführer for assault and battery. The indictments are the outgrowth of the shooting of Samuel W. Dowden, an attorney, by the police. On June 8, while riding in an automobile with W. Richardson Sinclair, Mr. Dowden was shot in the leg. The three police officers were in an automobile pursuing Mr. Sinclair's car, asserting that it was violating the speed law and that the driver refused to stop when signálled. The case created much indignation, the Indianapolis newspapers uniting in demanding that the chief of police be removed for sanctioning the shooting. After considering the matter, Mayor Bookwalter said that while he realized the shooting had been indefensible and unjustified, he did not believe he would be justified in discharging the chief, because of the large number of speed violations that had occurred.

# Rhode Island's New Garage Law in Force.

The new garage law of Rhode Island, which requires every garage owner to keep an accurate record of every car arriving at and leaving his garage, went into effect the last week in June. The measure was framed to protect automobile owners against unauthorized use of their cars, but it will also afford a means of tracing stolen cars. The forms on which the records are to be kept have been prescribed by the State Board of Public Roads. They contain spaces for the registration number of each car, the name of the operator and the exact times the car enters and leaves the

garage. Violations of the law are subject to a fine of not more than \$100 or imprisonment for not more than thirty days, or both.

### Connecticut Bill Passed by Senate.

The Connecticut Senate on June 29 added an amendment to the pending automobile bill, according to which automobile manufacturers in the State must pay a tax of \$1 each for all test cars driven on the State roads, and another amendment providing an annual tax of \$10 for liverymen who use automobiles in their business. The Senate then passed the bill and returned it to the House.

# New York Municipal Autos to Be Sign-Marked.

The ordinance introduced by Alderman B. W. B. Brown in the New York City Council to mark municipal autos so plainly as to prevent official joy riding, which was defeated two weeks ago, was adopted on Tuesday, 40 to 3, by the Board of Aldermen. A penalty of \$50 is provided for using a city auto without the distinguishing mark.

### Legal Notes.

The Supreme Court of Ohio on June 23 decided that the State automobile license law prevents cities from exacting a license fee from motorists. The city of Cincinnati formerly charged a fee of \$5 annually, and a similar fee was charged in Columbus, Ohio.

Judge Whallon, of the Indianapolis Police Court, has decided that physicians answering emergency calls in automobiles are not amenable to the law regulating speed. In two instances during the last week he has discharged physicians arrested for breaking the speed laws. There has been agitation for some time in favor of such a ruling.

The motorists of Paducah, Ky., have sent a petition to the city council asking for an increase in the speed limits effective within the city. The present ordinance limits the speed to 10 miles per hour on Broadway between First and Seventh streets, and to 6 miles per hour in turning corners, and the motorists request that the limit on Broadway be increased to 15 miles per hour.

The officials of the New Jersey Automobile and Motor Club, with headquarters in Newark, have asked the automobilists of Trenton to assist them in restraining Justice of the Peace Abram D'A. Naar, father of ex-Justice Manfred Naar, who was removed from office because of the complaints of the A. C. A., which proved that he issued summonses by mail, and also collected fines in the same manner. The Newark Club alleges that Abram D'A. Naar is pursuing the tactics of his son, and that a speed trap is in operation between Hightstown and Trenton.

Mayor Wheeler of Utica, N. Y., on June 25 sent a letter to Commissioner of Public Safety Church ordering that official and the police department to enforce the automobile speed law. The mayor says that he has received many complaints of reckless speeding.

The commissioners of parks of San Francisco on June 23 passed new rules regarding the operation of automobiles in these parks. All drives in the parks will hereafter be open to motors, except the avenue in the Panhandle and the road encircling the Stadium

In compliance with the Iowa law, which requires dealers to secure new licenses on July 1 of each year, sixty-five dealers filed application with Secretary of State Hayward in Des Moines on June 28. Last year 290 dealers' permits were issued in the State, and it is thought that the number this year will reach 300.

According to a recent decision of the Appellate Court in Chicago it is as much the duty of the driver of a motor truck to look behind him when he starts to back as it is to look forward when he starts his car forward. The court affirmed a judgment of \$10,000 given in the Superior Court in favor of Clinton Pierson against Lyon & Healy. The plaintiff was the conductor of a street car into which a motor truck owned by the defendant was backed. Pierson received a compound fracture of the left leg.

The city council of Knoxville, Tenn., has passed an ordinance regulating the operaion of horse and motor cabs. Motor cabs cannot be operated by persons under eighteen years of ago. The fare between any two points in the city of Knoxville will not exceed 50 cents. If the cab is detained by the passenger for any reason the charge for such detention shall not be more than at the rate of \$1 per hour. Violations of the ordinance are misdemeanors, and are subject to a fine of not less than \$5 and not more than \$50.

### The Plainfield (N. J.) Hill Climb.

A hill climb on Johnston's Drive, Plainfield, N. J., was the feature of the second day's program of the Charter Day celebration in that city on July 6. A considerable number of cars participated and large crowds lined the course. The upsetting of one of the automobiles almost resulted in a tatality. George Weldon and William Bolen, both of Rahway, in a National car, were just making the last hairpin turn within a few yards of the finish when the car leaped off the road and struck a wooden culvert, turned turtle, and went over an embankment. Weldon and Bolen were thrown out, the former receiving a badly lacerated scalp wound and a deep cut in the face, while Bolen's shoulder was fractured. They were both taken to Muhlenberg Hospital. The course was sevententlis of a mile, with nine difficult turns and an average grade of 15 per cent. The summaries:

First Event-For cars selling for not over \$850:

Won by Maxwell, 22 h. p., driver William Sichinger; second, Maxwell, 22 h. p., driver A. See; third, Hupmobile, 16 h. p., driver R. D. Martin. Time. 1:281/4.

Second Event-For cars selling for not less than \$851, nor more than \$1,250; Won by Buick, 34 h. p., drivers Warren and Easter; second, Overland, 30 h. p., driver George Reese. Time, 1:44.

Third Event-For cars selling for not less than \$1,250, nor more than \$2,000: Won by Marion, 35 h. p., driver Charles Stutts; second, Herreshoff, 24 h. p., driver George Robertson; third, Buick, 24

h. p., driver C. S. Dutcher. Time, 1:36 4-5.
Fourth Event—For cars selling for not less than \$2,000, nor more than \$3,000: Won by Chalmers-Detroit, 40 h. p., driver George Rankin; second, Palmer-Singer, 60 h. p., driver F. C. Lescault; third, National, 35 h. p., driver George Weldon. Time, 1:29 2-5.

Free for All-Won by Stearns, 40 h. p., driver John H. Rutherford; second, Chalmers-Detroit, 40 h. p., driver George Rankin; third, Simplex, 50 h. p., driver William Heitmeyer. Time, 1:28.

Winners' Class-Won by Chalmers-Detroit, 40 h. p., driver George Rankin; second, Maxwell, 22 h. p., driver William Sichinger. Time, 1:28.

### Columbia Motor Car Company Now in Possession of E. V. Company Business.

The reorganization of the Electric Vehicle Company, of Hartford, Conn., has been completed. The new concern, the Columbia Motor Car Company, elected its officers on June 30, and the business of the old company was transferred to it on the same date. The following officers were elected: Herbert Lloyd, of Philadelphia, president, Henry W. Nuckols, vice president, treasurer and general manager; Herbert Lloyd, of Philadelphia; Henry W. Nuckols, Walter G. Henderson, of Philadelphia; William Hooker Atwood, of New Haven, and Kenneth B. Schley, of New Vork directors

The new officers directly after their election took over the assets of the old company, with the exception of the cash in bank, which is to be used in paying dividends to creditors. The Morton Trust Company, of New York, trustee for the bondholders, has released the \$2,500,000 mortgage on the plant at Hartford, and the bondholders will share with the unsecured creditors in a pro rata distribution of the proceeds of the sale of the property. A dividend of 20 per cent. is now being paid. The receivers have not yet been discharged by the court, but will continue in their positions until all the proceeds have been distributed among creditors.

According to reports circulated in Wall Street, the basis of the reorganization so far as the stockholders were concerned was as follows: Holders of the common stock paid \$1 and twenty shares of the old stock for one share of the new stock. Holders of preferred stock also exchanged twenty shares of the old company for one share of the new company, but did not pay a bonus. The new company is capitalized at \$2,000,000 preferred stock, compared with \$9,000,000 preferred in the old company, and \$1,000,000 common stock, against \$11,000,-000 in the old company. The holders of the company's \$1,521,000 bonds are to be given

\$620 in new preferred stock for every \$1,000 bond

### Increase in the Production and Price of Crude Rubber.

The entries at the port of Para for the crop year which ended July 1 of rubber of all grades, including Caucho, have exceeded all previous records for similar periods. The figures for the year are available only to June 28, and it is probable that the remaining days of the month will show that sufficient rubber was brought into Para to bring the total beyond the record figure of 1906-7. The statistics for several years past have been: 1901-2, 30,000 tons; 1902-3, 28,850 tons; 1903-4, 36,580 tons; 1904-5, 33,060 tons; 1905-6, 34,390 tons; 1906-7. 38,005 tons; 1907-8, 36,650 tons; 1908-9, up to and including June 28, 37,970 tons.

The steady increase of consumption in rubber for some months past has stimulated shipments from the plantations into Para to such an extent as to leave smaller stocks than usual at the plantations for future shipments, and the rubber consuming trade will, therefore, be obliged to depend wholly upon the stocks already shipped from the Amazon, while awaiting the next crop, the first shipments of which will not reach Para before the end of the summer.

The price of rubber has advanced considerably within the past year, as may be seen from the following New York quotations for Para grades of one year ago, one month ago and for June 29:

month ago and for	june 29	9:

### New Late Ferry at Rye, N. Y.

Pursuant to a demand made by automobilists for a late trip of the ferryboat Englewood, running between Rye and Sea Cliff, across Long Island Sound, the management of the line have decided to make one extra trip at night, leaving Rye, N. Y., at 8 p. m. and Sea Cliff at 9 p. m.

The Jacobson-Brandow Company, of Pittsfield, Mass., has secured the contract for 3,000 four cylinder coils for the 1910 output of the Hudson Motor Car Company. of Detroit. The contract is said to amount to about \$45,000.

A deed transferring the property of the Eisenhuth Horseless Vehicle Company, of Middletown, Conn., to the Noiseless Typewriter Company was filed on June 30 by Attorney Culver.

### A Device Designed to Prevent Sooting.

By J. S. V. BICKFORD.

I had a conversation with the tester of a large factory the other day, and he drew my attention to a peculiarity of the modern car. He said: "Have you ever noticed that sooting of pistons and cylinder heads is a modern complaint?" I remarked that I had not noticed it before, but when he brought it to my mind I did recall that some of the old cars which I had driven did not suffer from sooting. He told me that this was almost universally true.

Take the case of the old Panhards built back in 1902, for instance; not only did these cars not soot in the days when they were new, but they will not soot now, so that it cannot be a question of the quality of the gasoline or oil used. This is a curious phenomenon and one worthy of some attention. Why should the modern car soot its pistons and its elder brother not? The explanation must, of course, be sought in the points of difference between the two. Now, as to manufacture, there cannot be a great difference; the only thing possible is that the old cars had no ground cylinder liners and the new ones have; but it is difficult to account for matters on these lines. Compression is not much different. The old obsolete Wolseley car, for instance, had every bit as high a compression as the modern car; and even if the compression were a little higher now than formerly it is difficult to believe that a few pounds up or down could make the difference, otherwise one would expect that a leaky set of valves would make for the absence of sooting, and I have never heard of such a fact being noted.

The next point of difference to be noted between the old engine and the new is flexibility. The old engine had no flexibility; the new one has much. The old engine would scarcely run below half its maximum rate of speed; the new will run down to a fifth or less. Now, everyone who has examined a carburetor for slow running will have noticed that in order to get the slowest running of the engine a rich mixture is necessary, probably because the incoming charge is much diluted with burnt gases. Here, then, we have a pointer. A rich mixture would certainly make for soot on the piston head, as everyone knows who has been troubled with too large a carburetor jet, and it would seem that this might be the cause of the trouble.

If we are right in saddling this peculiarity of the modern engine with the responsibility for sooting, from which even the very best and most expensive cars suffer, it is worth while to inquire whether anything can be done to get rid of the trouble. It is necessary, therefore, to make one or two assumptions. Why should it be necessary to use a strong mixture for

slow running, occasioning as it does occasional black puffs of smoke from the exhaust?

Am I right in supposing that it is due to the burnt gases? If so, the only thing to do is to get rid of these gases or some of them, which points toward the scavenging charge with its reduced power.

Possibly, however, a compromise might be made. The richest mixture will probably be used when the engine is turning over doing no work, and as a matter of fact my own experiments point to this conclusion. If, then, we could insure the engine turning over "idle" with a weak mixture, we should probably do much to get rid of sooting.

Now the reason why an engine will not run at very slow speeds is, I believe, the

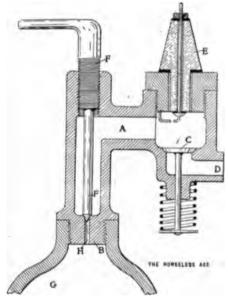

Fig. 1.

dilution to which I have referred, so that the problem we have to solve is the use of a sufficiently rich mixture round the sparking plug points to insure explosion, and at the same time the introduction of such a small amount of this mixture that neither soot will be deposited nor the engine driven above the minimum speed. In order to accomplish this it is obvious that we must, by some means, have a "cloudlet" of very good gas just round the plug points, and if, as is probable, this little cloud of gas has to be rich, then we must have excess of air in the immediate neighborhood to oxidize any soot formed by the explosion.

I beg to offer the device shown in section in Fig. 1 as a solution of the problem. I have already shown it to one competent engineer, who thinks that it might work all right.

Here A is a small chamber, of which the capacity would be determined by experiment, screwed into the sparking plug hole B of the

auxiliary ignition. (I shall speak later of the method of working where only one ignition is used.) C is a small automatic inlet valve communicating by the pipe D with a small carburetor, which may be of the wick type, as it will only have to supply very little gas. E is the auxiliary sparking plug and F is a screw down stop valve which, when screwed down, closes communication between the engine cylinder G and the cavity A.

The main carburetor throttle will be so arranged that when more than fully closed a hole will be opened to admit clean air to the cylinders, the size of this hole being determined by experiment.

The action of the device will be as fol-

On switching on the apparatus, which will be done by closing the main throttle and opening the screw valve F, the engine begins to draw clean air through the main throttle, and at the same time a rich mixture through the pipe D and the valve C. The sizes of the pipes and carburetor will be such that only about enough gas will be drawn in through D to fill the chamber A. On the compression stroke this gas will be compressed, together with a little of the air already introduced through the main throttle. The mixture thus diluted will be exploded by the spark of the plug E at the right time, and the resulting flash of flame will shoot down through the hole H into the clean air in the cylinder, where any unconsumed carbon and gases will be oxidized.

It seems to me that if this apparatus were carefully designed an engine might be made to run at almost any low speed, for the compression could be much reduced and still the mixture in the chamber A would be rich enough to fire with certainty.

The method of coupling up such a piece of apparatus on a four cylinder engine could safely be left to the designer, but I might suggest that if all four of the screw valves F were coupled up to one connecting rod projecting through the dashboard of the car, which could easily be done, then one pull or push on this rod would open all four (or six) valves and start up all the auxiliary explosion chambers at once. Thus, in such a car, as soon as the driver desired to stop, he would merely close his throttle and press the end of the control rod with his foot, when the auxiliary apparatus would at once come into play.

Should only one ignition system be used then it would be perfectly easy to arrange matters so that the motion of the rod coupling the valves would also throw the high tension wire from one plug to the other.

I believe that this apparatus would be well worth considering. Among other things it lends itself to the attention of the specialty man, for the explosion chambers if made to fit standard sparking plug threads could be fitted to any car with little trouble.

# OUR FOREIGN EXCHANGES ➤

### New British Motor Fuel.

hen the plan of the British Governt to impose a tax upon gasoline for n pleasure automobiles was announced. as predicted that this would lead to ievelopment of new fuels, as well as to perfection of carburetors so as to renthem more economical. Whether these ictions will come true or not, there already signs that promoters of new iretors and of fuels other than gasoline take advantage of the impending ine in the price of gasoline, and already w fuel, referred to as Homoil, is being lded in the press. This fuel, which is to be produced from coal tar, in Great in is subject to the same taxation as line, but it is claimed to be cheaper to contain more heat units than gaso-

It would seem from the somewhat e description of the fuel given in our ish contemporaries that the product is other than the well known benzol. rder to put it prominently before the ic a number of press representatives : taken in cars operated on this fuel 1 London to Mitcham. It is estimated 180,000,000 gallons of the fuel could roduced annually in the United King-It is stated that a particular make arburetor, known as the Grunewald, to be used for this fuel. The latter f the surface type, the fuel being abed by the air by passing the latter a large number of non-absorbent balls. th are kept moist by a constant supply he fuel. The specific gravity of the is 0.885. It is claimed that the Ger-Government use the Grunewald cartor in connection with a fuel similar to soil for their marine and military truck

: on Visiting Cars in England. ouring in Great Britain by nonish motorists who bring their cars g with them will be considerably more nsive next year if the budget propoof Chancellor of the Exchequer Lloyd rge are adopted. It is proposed by him lace a duty of \$10 to \$200 on visiting according to horse power. In addito the license for the car the visiting orist would have to pay a registration a license fee and a tax for the chaufas a male servant. This would make outlay which might reach the sum of , which would be practically prohibitive re only, say, a week's stay in the counis considered.

ne same proposal of imposing a tax ion-resident motorists was made in the ich Chamber of Deputies about a year the sponsors of the bill holding that gners might just as well pay for use of French roads as natives. It

was soon made clear to the deputies, however, that France derives great profit from the wealthy visiting motorists, and that it would be extremely unwise to place the least obstacle in their way or to curtail the inducements attracting them to France. The bill was killed.

Following the example of Berlin, the city government of Cologne has placed in service a motor truck for the removal of dead horses, etc. The vehicle is equipped with a 28x32 four cylinder motor and capable of carrying up to one and one-half tons useful load.

At a council meeting of the Society of Motor Manufacturers and Traders, held on June 17, applications for sanctions for automobile shows in Manchester, Dublin and Liverpool were considered. The association unanimously resolved that at present no other automobile shows than Olympia and Edinburgh are desirable, and no sanctions will be given for other shows.

According to the official statistics about 1,200 automobiles are at present owned in Sweden, almost one-half of them in Stockholm. One hundred of the latter are taxicabs, and the number of these cabs is rapidly increasing since the opening of the Art Trades Exhibition early in June. There are 334 horse cabs in service in the Swedish capital, but the owners of such cabs are constantly changing them for motor cabs. The city council recently increased the speed limit for these vehicles from 15 to 20 km. per hour.

According to a report of the English Board of Trade, there has been an enormous increase in the importation of gasoline into the United Kingdom recently. No less than 11,009,977 imperial gallons were imported during the month of May last, as compared with 5,860,150 gallons in May, 1908, and 5,781,465 gallons in May, 1907. The enormous increase in the importation is ascribed partly to the growth of the automobile movement, and partly to the threatened taxation of gasoline for use in pleasure vehicles. The total amount of gasoline imported during the first five months of the year was 27,996,235 gallons, while during the same period of 1908 only 13,674,397 gallons were imported.

The automobile service between the cities along the coast of Austria, along the Adriatic Seasand Cetigne, the capital of Montenegro, has been discontinued owing to a strike of the chauffeurs. The automobiles in this service carried the mails, and in order to keep up the mail service it was necessary to return to the old horse diligences, which require six hours for the trip over the artificial road between Cettaro and Cetigne, which is covered by the motor buses in two to three hours.

### Alcohol Buses in Madagascar.

An extended trial with the object of introducing the use of alcohol as fuel for the motor buses which are being operated in Madagascar has been made recently. Since January I last the motor bus service has been an auxiliary of the railroad service of the island, and within several months it will cover a route nearly 100 kilometres in length, ending at Antananarivo and the terminus of the railroad. These tests are said to have proven exceedingly satisfactory. The best results were obtained with a 90° alcohol mixed with 40 per cent. of benzol. The tests were made on a 15 horse power Panhard-Levassor car which weighed about 5,500 pounds. The fuel consumption per hour was 6.62 litres, which works out to 0.121 litres per ton-kilometre (21.5 ton-miles per U. S. gallon). The average speed was 21.92 kilometres (14 miles) per hour. These results are practically equal to those obtained with gasoline. The Central Distillery at Antananarivo, in accordance with a contract made with the Government, furnishes the litre of alcohol-benzol mixture for 0.78 franc, that is to say, at a considerably lower price than that asked for gasoline at Antananarivo, viz. 1.33 francs. At the present time the vehicles used in the motor service are operating on alcohol. It might be added that a decree issued on March 7, 1908, made alcohol manufactured in the colony and intended for industrial purposes, tax free.

# Glidden Tour Preliminaries at Detroit.

The Detroit Automobile Dealers' Association will hold a big banquet at the Hotel Pontchartrain Friday evening at which the Governor of Michigan and the mayor of Detroit will be honored guests. Invitations have been extended to all of the A. A. A. officials, and the Glidden tourists will be present. On Saturday evening the Automobile Club of Detroit will give a dinner at its country clubhouse to the A. A. A. directors. The monthly meeting of the executive committee, to which the directors have been invited by President Speare, will be held Saturday morning at the Hotel Pontchartrain, which will be the official headquarters.

W. O. Lum, of Amsterdam. N. Y., has recently brought out a patch for inner tubes known as the "Everstick" patch. He has now changed the name to the "Quicktite" patch, and is organizing a company for its manufacture. The patch is covered with a brown cement preparation on one side. When a repair is to be made, the surface of the tire around the puncture is cleaned with gasoline and the cement covered side of the patch likewise. Then the patch is pressed in place and the job is done.

### MINOR MENTION

The branch managers of the Winton Motor Carriage Company held their annual convention in Cleveland last week.

The McFarlan Company, Connersville, Ind., are building models of a touring car and a roadster, to sell at about \$2,500.

The Willen Manufacturing Company has been organized at Auburn, Ind., to manufacture automobile tire protectors. W. H. Willenar is at the head of the concern.

Next year the horse power of the \$3,000 Moon car will be increased from 35 to 40, and in addition the company will make a \$1,500 car rated at about 30 horse power.

A deal for the sale of the Twyford motor car shops in Brookville, Pa., to New York capitalists, who plan to manufacture motor driven farm machinery, is said to be under way.

The Reliance Motor Company, Owosso, Mich., has asked the city council to close Howard street for three blocks and Michigan avenue for one block to enable it to enlarge its plant.

It is reported that the American Motor Car Company, of Indianapolis, which built 200 cars this season, plans to turn out 300 for 1910. Deliveries of the 1910 models will begin on September 1.

A new company will take over the St. Louis Car Company, which will discontinue the American Mors to make a new six cylinder car of American design, with a motor of 50 horse power. The general manager is H. E. Walton.

The Ewing Automobile Company, of Geneva, Ohio, which employs about 100 men, is said to be planning to move away from that city because there are no amusements there, and it is impossible to keep machinists there. Erie, Pa., is said to be considered favorably as a location.

The Gemmer Manufacturing Company, Detroit, Mich., has just completed an addition to its factory building, 80x275 feet, of trussed steel and with concrete flooring. The company will shortly break ground for two other additions, which when completed will give it 200,000 square feet of floor space.

The Detroit Automobile Dealers' Association is strictly opposed to automobile track racing, and though it has been approached a number of times by promoters to give its consent to such races it has always refused to do so. The reason given by the association for its stand in the matter is that such races are entirely too dangerous.

Two high priced cars belonging to A. B. Leach, South Orange, N. J., were destroyed by fire on June 28, and about \$500 damage was done to the concrete private garage of Mr. Leach, which is built in the shape of a small railroad round house. The cause of

the fire is unknown. One of the cars stored in the building was saved by the chauffeur.

The Austin Automobile Company, Grand Rapids, Mich., are considering to locate in Elwood, Ind., in the old factory of the Pittsburg Plate Glass Works.

The Hartford Rubber Works Company, of Hartford, Conn., have adopted the Dow standard remountable rim, which they will market in connection with their Hartford automobile tires.

Klein & Mercer have established themselves as expert body draftsmen at 1777 Broadway, New York, and will prepare drawings for automobile bodies for both commercial and pleasure vehicles.

At a meeting of the rural free delivery mail carriers of York and Adams counties, Pa., at York, Pa., on July 3, State President C. C. Rich, of Lewisberry, spoke on the use of the motorcycle in rural mail delivery.

The Mitchell factory at Racine, Wis., was temporarily shut down on June 30 to take an inventory and to give the employees a chance to take part in the home coming celebration. Work will probably be begun again on July 8.

The East Oak Park Neighborhood Club of East Oak Park, near Chicago, have sent a petition to the village board in which they request the trustees to stop the erection of a garage in that section by Village Trustee T. L. Gongren of Oak Park.

The Model Automobile Company, Peru, Ind., have doubled their original capitalization, and decided to immediately erect two additional buildings which will give them 35,000 square feet additional floor space. We are informed that the additional capital stock was taken up by the old stockholders.

A fire which broke out during the night of June 29 did considerable damage to the garage of S. H. Peterson, Chicago, Ill., who handle the Pope-Waverley and Jewel cars; also to the plants of the Auto Tire Security Company and of the Chicago Coach and Carriage Company. The cause of the fire is unknown. The damage is estimate at \$20,000.

The Cleveland-Canton Spring Company, of Canton, Ohio, have recently occupied a new addition to their factory, which will be devoted entirely to the manufacture of automobile springs. The company has installed special gas heated kilns, which can be kept at a uniform temperature and in which the steel bars never come in contact with the flame for the heat treatment of their spring material.

R. R. Kimball, a well known Omaha, Neb., dealer, has had a special landaulet body built for a Cadillac "30" chassis, which he is now exhibiting at his garage. The interior is very luxuriously upholstered in Bedford whipcord, and has carpet, French trimmings and silk window shades. It is also fitted with card and perfume cases, and is equipped with electric lights, speaking tube and two special automatic folding seats. The wind shield is so constructed that when it is folded up it fastens to the

roof, and thus does not occupy any useful space.

Governor Fort of New Jersey is reported to have purchased an Oldsmobile Model D touring car from R. C. Manning, Oldsmobile agent at Trenton.

We are informed that the State Legislature of New Jersey recently made an appropriation for the purchase of a 45 horse power Rambler car for the use of the Executive Department of the State government.

The Northway Motor and Manufacturing Company, Detroit, Mich., has filed notice that at a meeting of shareholders it was voted to increase the capital stock of the company from \$100,000 to \$250,000. All of the increase has been paid in in cash.

The Davis Manufacturing Company, Park and Fifteenth avenues, Milwaukee, Wis., builders of motors and parts, have taken out a permit for the erection of a \$12,000 addition to the factory. The company last year erected large works at Park and Fifteenth avenues, and abandoned the plant on Sixth street, but the new quarters already are too small.

The office, accounting department and retail salesroom of the Auto Tire-Security Company, manufacturers of Kemizite, at 1231 Michigan avenue, Chicago, were slightly damaged by fire last week. The actual loss was trivial, and the retail department was doing business again in the garage three hours after the fire. The wholesale department is temporarily located at 1221 Michigan avenue.

Business men and automobile owners of Fort Wayne are trying to raise funds for a speedway near that city, and which, it is expected, would cost about \$200,000. The plan is to build a course about 20 miles long, near Fort Wayne, and hold a number of racing events. The proposed course would run 8 miles west of Fort Wayne, then go 4 miles south and return to Fort Wayne by another route.

It is reported that George Schebler, of Wheeler & Schebler, Indianapolis, is planning a racing car to be equipped with a twelve cylinder engine. It is said the engine will be rated at about 100 horse power, and that the cylinders will be of the double opposed type. The company has announced that it will give a \$5,000 silver trophy in connection with races on the Indianapolis motor speedway, and it is supposed the new car will participate in the events.

The main office of the Spare Motor Wheel of America, Ltd., has ben moved to the factory at St. Ann, Ill. The firm has gone into the manufacture of standard clincher automobile and motorcycle rims, in addition to the manufacture of the Stepney wheel. They also manufacture the Universal demountable rim of the Universal Rim Company, of Chicago. The American Distributing Company, of Indianapolis, Ind., will handle their entire output of automobile rims.

Up to June 15, 3,611 automobiles had been registered in the State of Washington.

Seventeen inspectors and four revenue agents on the denatured alcohol rolls of the Internal Revenue Bureau have been dismissed because their services are no longer needed. The use of denatured alcohol, especially in internal combustion engines, has not developed as rapidly as was expected.

The Carl Spoerer Sons Company, of Baltimore, Md., have just completed their 1910 demonstrating cars. They will produce two models during the coming year, viz., a 30 horse power and 50-60 horse power. The company exhibited their first machine at the Baltimore show last winter. Ten of these cars are now in course of assembling.

Following the precedent set last year, the Carriage Builders' National Association is again inviting manufacturers of automobile parts, accessories, etc., to exhibit at the C. B. N. A. national exhibition, which will be held in conjunction with their annual convention during the week of October 18 to 22, 1909, at Washington, D. C. Henry C. McLear, secretary of the association, Wilmington, Del., is manager of the show.

### Club Notes.

The A. C. A. has issued a pamphlet giving specific route directions for a tour through the Adirondack Mountains to Lake Champlain.

The Kearney (Neb.) A. C. is at present being organized by a number of motorists of that city, headed by Dr. C. K. Gibbons. A preliminary meeting was held at the City Hall on June 28.

The Plainfield (N. J.) A. C., which was recently organized with nineteen charter members, has elected the following officers: Dr. F. C. Ard, president; H. W. Marshall, vice president; J. H. Rankin, secretary, and F. O. Ball, treasurer.

The San Francisco Motor Club is planning a tire changing contest, to be held over a course around the bay, and to be combined with an economy contest. The details will be decided upon at the next meeting of the club.

Chairman Powell Evans, of the A. A. A. Touring Board, and president of the A. C. of Philadelphia, sailed last week to attend the annual Congress of the International League of Tourists' Associations, which will be held in London July 7 to 9.

H. L. Kramer, of Mudlavia, Ind., is endeavoring to interest Indianapolis drivers in making an endurance run to that resort under the auspices of the A. C. of Indiana. The club is planning a run some time during the fall, but it has been planned to run it to French Lick, which was the destination of the annual run last year.

The Denver Motor Club has retained Grant L. Hudson as attorney to defend the members of the club in test cases which have been brought in the anti-speed crusade now being carried on by the Denver

fire and police board. Since the crusade was inaugurated there have been a considerable number of arrests for speeding every day.

The Automobile Club of Cheyenne, Wyo., is building a 4 mile automobile speedway, and expects to hold a track meet on August 17.

The Springfield (Mo.) A. C., which has led a passive existence during the past two years, has decided to enter upon an active career, and at a meeting on June 23 elected the following officers: W. H. Horine, president; Holland Keet, vice president; J. E. Atkinson, secretary; Robert L. Pate, treasurer. It is planned to make a tour to Kansas City to see the finish of the Glidden Tour there on July 28.

At a meeting of the board of the Cleveland A. C. on June 26 C. A. Otis was elected chairman of the finance committee of the national convention board and John Ehrhardt was chosen secretary. This board will make the arrangements for the National Good Roads Convention which is to be held in Cleveland in the fall. It is planned to raise between \$5,000 and \$6,000 for the entertainment of the delegates and other necessary expenses.

The Michigan State A. A. held its annual meeting at Detroit on June 24, at which the following officers were elected: Edward A. Skaes, Detroit, president; J. R. Jackson, Grand Rapids, first vice president; Dr. D. Emmet Walsh, Grand Rapids, second vice president; J. C. Hartfield, Kalamazoo, third vice president; Dr. F. C. Warmshuis, Grand Rapids, secretary, and J. J. Ramsay, Detroit, treasurer. A vote of thanks was tendered retiring President Edwin S. George.

### Business Troubles.

A creditors' petition in bankruptcy has been filed against the International Generator Company, manufacturers of gas equipments for automobiles, motor boats, etc., at 244 West Forty-ninth street, New York, by Henry M. Reichenbach, of Yonkers, upward of \$3,000; William Shrive, of Yonkers, \$84, and Howard W. Beach, of East Orange, N. J., \$47. Preferential payments are alleged as acts of bankruptcy, and the concern is said to be owing upward of \$1,000. Judge Hand appointed Hamilton M. Dawes temporary receiver.

### Garage Notes.

Raban & Johnston, whose garage on Broad street, Portchester, N. Y., was burned last year, have opened a new fireproof garage on the same site.

Benjamin J. Hughes, Newark, N. J., has filed plans for a \$7,750 garage on Park avenue near North Eleventh street. The building will be 46x100 feet.

The International Automobile Co., Chicago, Ill., has moved to 2336 Wabash avenue, where it occupies a two story concrete building 55 feet wide by 175 feet deep.

The Cook-Buchanan Co., of Lake Mills, Wis., has erected a two story garage on Main street, Lake Mills, for the use of Seaver & Gericke, a

new agency, repair and garage concern. The entire basement will be devoted to repairs, and the first floor for storage and show rooms. This is the first garage in Lake Mills.

The new garage of A. E. Annett, located on Woodward avenue, Detroit, is nearing completion. A special feature of this garage will be an unusually complete repair shop.

usually complete repair shop.

Herman Heller and P. F. Dolan, of Shawano,
Wis., have purchased the Mehlhorn Building on
Main street, and opened a garage under the name
of Heller & Dolan Automobile Co.

M. C. Huie and A. J. Langford have purchased the garage and repair shop conducted under the name of the Columbia garage in Atlanta, Ga., which holds the agency for the Ford cars.

which holds the agency for the Ford cars.

E. W. Masterson, of Denver, Col., has bought the reinforced concrete garage of Horace B. Day, San Diego, Cal., for \$16,000. The garage is located on First street between B and D streets.

The W. L. Hibbard Motor Car Co., Milwaukee, Wis., State agents for the Chalmers-Detroit, Hudson and Thomas lines, has moved into its new garage on Wells street, between Third and Fourth streets.

For the Maxwell branch in Chicago a new four story structure, 80x160 feet deep, is being erected at Eighteenth street and Michigan avenue. It is hoped to have the building ready for occupancy by October 1.

The Jungclass Automobile Co., Cincinnati, Ohio, will build a garage at Reading road and Maple avenue, Avondale. The site is 70x50, and was purchased for \$7,500. The building will probably cost \$25,000.

The Autocar Agency in San Francisco has leased a site on the south side of Golden Gate avenue, between Van Ness avenue and Polk street, on which a reinforced concrete building will be erected for its San Francisco headquarters.

The McCurdy-May Motor Co. has been organized in Pittsburg to handle the Pierce-Arrow cars, and have secured headquarters in the former home of the Fort Pitt Automobile Co. on Baum street. E. C. McCurdy is secretary of the company.

Henry Kappelman is remodeling the livery barn of the Wisconsin House at Two Rivers, Mich., to use it as a garage and salearoom for automobiles. The building will be provided with a glass front. A stock of accessories and supplies will also be carried

The Maxwell-Briscoe Motor Co. have established a branch office in Philadelphia, and the Longstreth Motor Car Co., which formerly held the Maxwell agency in that city, relinquished it on July 1. Wm. F. Smith will have charge of the retail and wholesale business of the new branch, which will be conducted in the same quarters as heretofore.

The Philadelphia Studebaker branch, of which E. V. Stratton is manager, has taken over the rest of the allotment of E-M-F cars of the Foss & Hughes Co., the former E-M-F dealers. Hereafter the E-M-F car will be handled exclusively from the Studebaker salesrooms at 530 North Broad street. The transfer of an agency contract took effect on July 1.

The Motor Car Agency of Seattle have commenced the construction of a fireproof building at the corner of Broadway and Union street, where their salesrooms, garage and shop will be located. The building will be equipped with every modern facility, and will contain a floor area of 7,000 square feet. Fred Haines is manager of this new concern, and will handle the Pierce-Arrow lines during 1910.

John S. Lazarus, an Indianapolis capitalist, has built a garage in the heart of the residence district in order to give his two sons something to occupy their time. The garage is of reinforced concrete construction, of artistic design, and has no interior posts. It is well lighted by electricity, and is equipped with modern appliances for washing and caring for cars. S. A. Kepler, an expert machinist, has been employed. The plan of a public garage in an exclusive residence neighborhood is new in Indianapolis.

### **MOTOR VEHICLE PATENTS**

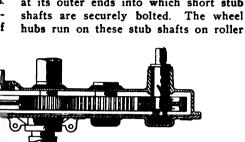

Reviews of Specifications.

921,705. Timing Gear Mechanism for Explosive Engines.-Lindley D. Hubbell, of Hartford, Conn., assignor to the Pope Manufacturing Company, Hartford, Conn. May 18, 1909. Filed April 27, 1908.

This invention relates mainly to provisions whereby the enclosing casing of

Propelling Mechanism for 022,372. Motor Driven Vehicles - Alexander Winton and Harold B. Anderson, of Cleveland, Ohio, assignors to the Winton Motor Carriage Company, Cleveland, Ohio. May 18, 1909. Filed October 30, 1906.

This invention relates to a live axle construction in which the load carrying and power transmitting members are separate. The load carrying member is of I section, and is provided with hubs at its outer ends into which short stub shafts are securely bolted. The wheel

No. 921,705.

the gearing for the cam shafts, magneto and pump is rendered oil-tight. In order to prevent the oil in the gear case from working through the various bearings the journals are provided with inclined grooves near their ends, in such a manner that when the cam shaft rotates the grooves collect any grease trying to escape through the bushing around the shaft and forces it back into the gear case. The cam shafts terminate within the gear case, and only the crank shaft extends through it, and the opening of the case for the crank shaft is rendered oil-tight by means of a stuffing box.

Vehicle Spring.—Lewis C. 921,947. Burnet, of Newark, N. J., assignor to

Burnet Compound Spring, Inc., Newark, N. J. May 18, 1909. Application filed August 24, 1907.

This spring is substantially a double elliptic spring, consisting of two elliptic springs, of which one is superposed upon the other. Each half of each elliptic spring consists of two or more leaves. The minor leaves of the upper and lower half are so arranged as to help the main leaf in carrying the load, while the minor leaves of the intermediate halves are so arranged as not to affect the load resting upon the main leaves of these halves, but to assist the main leaves in taking part of the load during the rebound.

bearings. The hubs are provided with combined brake drums and internally toothed gear crowns. With these internal gears mesh spur pinions which receive their power through shafts running parallel with the rear axle and provided with two universal joints each. The bevel driving gear and differential gear are carried in a housing supported from the carrying axle at or near the centre. A brake drum is supported independently of the driving mechanism, and the drum and propelling shaft have interlocking members.

### Patents Issued May 18, 1909.

921,656. Roller Bearing .- Herbert W. Alden, Canton, Ohio, assignor to Timken Roller Bearing Axle Co., Canton, Ohio, a corporation of Ohio. Filed April 15, 1907. Serial No. 368,314.

921,705. Timing Gear Mechanism for Explosive Engines.—Lindley D. Hubbell, Hartford, Conn., assignor to the Pope Manufacturing Co., Hartford, Conn., a corporation of Connecticut. Filed April 27, 1908. Serial No. 429,524.
921,710. Pneumatic Tire.—Grant Jacobs, Des

Moines, Ia. Filed March 13, 1908. Serial No. 420,941.

Transmission Gearing.-John M. Van 921,754. Dyke and Fayette R. Rowell, Canastota, N. Y. Filed September 8, 1908. Serial No. 451,951.

921,862. Vehicle Spring.-Edmon M. Mayhew, Mooresville, N. C., assignor of one-half to T. H. Pegram, Mooresville, N. C. Filed November 11, 1908. Serial No. 462,132.

921,933. Engine Starter.-Daniel C. Wilgus,

Los Angeles, Cal. Filed May 29, 1907. Serial

No. 376,350.
921,947. Vehicle Spring.—Lewis C. Burnet, Newark, N. J., assignor to Burnet Compound Spring, Inc., Newark, N. J., a corporation of New Jersey. Filed August 24, 1907. Serial No. 389, 945.

921,963. Automobile Vehicle.—Leonard H. Dyer, Washington, D. C., assignor to Enterprise Automobile Company, Hasbrouck Heights, N. J., a corporation of New Jersey. Filed February 3. Serial No. 3,880. Renewed September 22, 1908. Serial No. 454,155.

921,978. Compensating Gear.—Edwin J. Gould, Boulder, Col., assignor of one-fourth to James A. Walker, Boulder, Col. Filed April 3, 1908. Serial

No. 424,997.
921,994. Variable Speed and Reversible Gear.
—George P. Innes and Thomas Con Allen, Sydney, New South Wales, Australia. Filed May 18, 1908. Serial No. 433,508.

921,995. Auxiliary Starting Device for Automobiles.—James W. Jackson and Frank Jackson, Denver, Col. Filed December 18, 1908. Serial

No. 468,163.

Steering Mechanism for Vehicles.— 922,044. Steering Mechanism for Vehicles.— Albert F. Rockwell, Bristol, Conn., assignor to the New Departure Manufacturing Co., Brist Conn., a corporation of Connecticut. Filed November 3, 1905. Serial No. 285,730.

922,055. Automatic Swivel Lamp for Automobiles.—Julius O. Spang, Halleybury, Ontario, Canada, assignor of one-half to John Edward Hammell, Halleybury, Canada. Filed December 17, 1908. Serial No. 468,028.

922,145. Carburetor.—Albert Howarth, Providence, R. I., assignor to Standard Carburetor Company, Providence, R. I., a corporation of Rhode Island. Filed May 31, 1907. Serial No. **276,616.** 

928,278. Automobile Wheel.—Ole A. Hamre, Arriba, Col. Filed July 26, 1907. Serial No. 385,698.

922,284. Apparatus for Determining the Depth of Liquids.-Joseph W. Jones, New York, N. Y. Filed December 13, 1906. Serial No. 347,670.

922,299. Headlight Adjuster for Automo Leonard M. Leach, Fort Worth, Tex. January 18, 1909. Serial No. 472,779.

922,367. Driving Mechanism for Motor Driven Vehicles.—Samuel M. Vauclain, Philadelphia, Pa., assignor to Burnham, Williams & Co., Philadelphia, Pa., a firm. Filed June 20, 1908. No. 439,542.

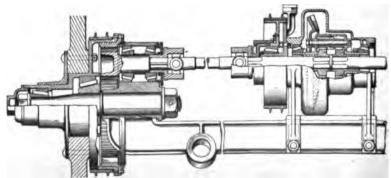

Propelling Mechanism for 922,372. Motor Driven Vehicles.-Alexander Winton and Harold B. Anderson, Cleveland, Ohio, assignors to the Winton Motor Carriage Co., Cleveland, Ohio. Filed October 30, 1906. Serial No. 341,268.

922,402. Demountable Tire Rim.—Alexander

Dow, New York, N. Y., assignor to Dow Rim Co., a corporation of New York. Filed December 30, 1908. Serial No. 470,052.

922,403. Locking Device for Demountable Tire Rims.—Alexander Dow, New York, N. Y., assignor to Dow Rim Co., a corporation of New York. Filed January 29, 1909. Serial No. 474,-989.

Demountable Tire Rim.-Alexander 922,404. Dow, New York, N. Y., assignor to Dow Rim Co., a corporation of New York. Filed January 29, 1909. Serial No. 474,990.

No. 922,372.

### Patents Issued May 25, 1909.

922,454. Vehicle Spring.—Lewis C. Burnet, Newark, N. J., assignor to Burnet Compound Spring, Inc., Newark, N. J., a corporation of New

Jersey. Filed September 11, 1908. 922,489. Motive Power for Automobiles, etc. Edward S. Lea, Trenton, N. J., assignor, by mesne assignments, to Robert Wolstenholme, Philadelphia, Pa. Filed November 9, 1907. Serial No. 401.420. Renewed December 17, 1908.

922,528. Cut-out Attachment for Internal Combustion Engines.—Benjamin F. Sheibley and Wilhelm Moller, Lewistown, Pa. Filed April 25,

Tire Tool.-Tames A. Swinehart. Akron, Ohio. Filed May 29, 1908.

Muffler Cut-out Mechanism.-Lee S. 922,563. Chadwick, Pottstown, Pa. Filed March 8, 1909.
922,599. Reversible Transmission Gearing. 922,599. Reversible Transmission Gearing.— Moses W. Kouns, Columbus, Ohio, assignor to the

Ohio Manufacturing Co., Upper Sandusky, Ohio, a corporation of Ohio. Filed May 4, 1908. 022,604. Double Tank Fuel System .- Hermann Lemp, Lynn, Mass., assignor to General Electric Co., a corporation of New York. Filed August 1,

Pneumatic Tire.-Frank Reddaway, Pendleton, Manchester, England. Filed February 18. 1008.

Power Transmission Mechanism for 922,634. Motorcycles and Other Vehicles.—George W. Sherman, New York, N. Y. Filed November 14, 1908. Spring Wheel.-Elias B. Anderson, 922,658. Rock Falls, Ill. Filed June 25, 1908.

922,669. Spare Tire Cover.—Hyman Cohen, Brooklyn, N. Y. Filed December 21, 1908. 922,673. Ignition System for Internal Combustion Engines.—Mark B. Crist, Pittsburg, Pa., assignor to the Westinghouse Machine Co., a corporation of Pennsylvania. Filed February 15, 1906. 922,737. Spoke.—Thomas H. Walbridge, To-ledo, Ohio. Filed October 29, 1906. 922,739. Tire Protector.—Edward J. Weidner,

Lindsay, Neb. Filed October 15, 1908.

222,741. Exhaust Dissipating Apparatus for Motor Vehicles.—George E. Whitney, Boston, Mass., assignor, by mesne assignments, to Stanley Motor Carriage Co., a corporation of Massachu-

setts. Filed December 1, 1899. 922,752. Electric Train or Vehicle.—John L. Creveling, New York, N. Y. Filed March 26, 1903. 922,757. Steering and Turning Device for Vehicles.—John M. Eadie, New York, N. Y., assignor to Eadie Vehicle Gear Co., a corporation of New Jersey. Filed June 11, 1907.

922,764. Igniter Timing Device.—James G. Heaslet, Detroit, Mich., assignor to the Garford Co., Elyria, Ohio, a corporation of Ohio. Filed July 17, 1907.

922,826. Headlight.-Richard H. Welles, nosha, Wis., assignor to the Badger Brass Manufacturing Co., Kenosha, Wis., a corporation of Wisconsin. Filed September 19, 1907.

922,916. Brake Operating Mechanism for Motor Vehicles.-Paul Krause, Babylon, N. Y. Filed

August 26, 1908.
022,965. Clutch Gear for Hubs of Vehicles. Bernhard Settergren, Chicago, Ill., assignor to

John Gubbins, Chicago, Ill. Filed June 6, 1906.
923,043. Slip Coupling.—Edward J. Gulick,
Mishawaka, Ind. Filed July 11, 1907.
923,044. Gear Transmission Mechanism for Automobiles.—Edward J. Gulick, Mishawaka, Ind. Filed August 15, 1907.

923,045. Torsion Tube Support for Rear Axle Housings of Automobiles.—Edward J. Gulick, Mishawaka, Ind. Filed September 13, 1907. 923,046. Gas Engine.—Edward J. Gulick, Mish-

awaka, Ind. Filed May 27, 1907.
923,059. Vehicle Tire.—Allison M. MacFarland,

Philadelphia, Pa., assignor, by direct and mesne assignments, of fifteen one-hundredths to William W. Gibbs, one one-hundredth to Charles H. Heustis, and three one-hundredths to William W. Weigley, Philadelphia, Pa., and sixty-four one-hundredths to William C. L. Eglin and Joseph B. Mc-Call. Filed July 11, 1908.

923.073. Indicator for Liquid Fuel Tanks .-Sarah H. Peckham, New York, N. Y., assignor to

Hanks Gasoline Meter Co., New York, N. Y., a corporation of New York. Filed November 5, 1907.
923,104. Wheel Tire.—Anson R. Bangs, New
York, N. Y. Filed July 29, 1908.

Patents Issued June 1, 1909.

162. Shock Absorber for Vehicles.—Ed-923.162. Shock Absorber for ward A. Garvey and Christopher A. Garvey, St. Louis, Mo., assignors to the American Auto Ap-

pliance Co. Filed January 9, 1908.
923,167. Motor Vehicle.—Stephen B. Gray,
Jacksonville, Ill.; Bartlett S. Gray executor of said Stephen B. Gray, deceased. Filed July 14,

923,205. Wheel for Road Vehicles.—Feaster Shaw, Bishop Auckland, England. Filed January 18, 1908.

Steering Gear .-- Charles F. Strawn, 923,210. Philadelphia, Pa. Filed December 26, 1908. 923,230. Steering Gear.—Abram D. Wilt, Jr.,

Detroit, Mich. Filed November 25, 1908. 923,279. Pneumatic Tire.-Alexander Latimer, London, England. Filed June 8, 1907.

923,295. Continuous Track Light Attachment for Automobiles.—John M. Pitney, Jr., Lorain, Ohio. Filed January 11, 1909.
923,322. Automobile Tire Protector.—Andrew

B. Boughan, Chicago, Ill. Filed April 6, 1908. 923,332. Anti-Skidding Device.—Louis J. Clergy and Henry Morrow, Belt, Mont. Filed

January 21, 1908.

923,379. Inflation Valve.—Joun.

Litchfield, Conn. Filed August 1, 1907.

023,377. Carburetor.—Gustave F. Schmidt,

one-hundredths to Henry T. Teel, Richmond, Va., and one-half to the Cardwell Machine Co., Richmond, Va., a corporation of Virginia. Filed March 27, 1908. 923,422. Valve Operating Mechanism.—George W. Dunham, Lansing, Mich., assignor to Olds Motor Works, Lansing, Mich., a corporation of Michigan. Filed April 23, 1906.

923,436. Resilient Vehicle Wheel.—Herbert G.

Mackinney, Providence, R. I. Filed November 11,

Timer and Distributor.-Harry L. 923,442. Radford, Orange, Mass., assignor to Grout Brothers Automobile Co., Orange, Mass., a corporation of Massachusetts. Filed August 9, 1905.

923,443. Universal Joint.—Bert O. Rhodes. Kalamazoo, Mich., assignor of one-half to Clovis V. Salisbury, Kalamazoo, Mich. Filed November 20, 1907.

923,456. Anti-Slip Device.—William M. Stevenson, Indian Orchard, Mass. Filed February 7, 1008.

Variable Speed Gear .- Perry C. Wil-923.472.

liamson, Oakland, Cal. Filed May 19, 1908. 923,491. Explosive Engine.—Robert W. Coffee, Richmond, Va., assignor to Lewis M. Kelzer, Baltimore, Md. Filed May 8, 1908. Renewed March 20, 1000.

923,516. Resilient Tire.—Nels H. Hassel, Los Angeles, Cal. Filed October 28, 1907.

923,536. Internal Combustion Engine.—John A. Kitchen, Lancaster, England. Filed December 28, 1908.

Fluid Clutch Speed Controller and Power Transmitter.—Robert E. Newcomb, Holyoke, Mass. Filed March 7, 1908.

Combined Vibrator and Timer.-Wil-923,566. liam S. Newcomet, Philadelphia, Pa. August 24, 1908.

923,583. Steering Gear for Vehicles.—David E. Ross, Brookston, Ind., assignor to Ross Gear

and Tool Company, Lafayette, Ind., a corpora-tion of Indiana. Filed May 14, 1906.

923.613. Clutch.—Leonard Atwood, Philadel-phia, Pa., assignor of one-half to Albert L. Register, Ardmore, Pa. Filed May 11, 1907.

923,632. Motor for Automobiles .-- Mortimer Eastman and William Eastman, Roslyn, N. Y. Filed November 24, 1908.

923,636. Change Speed Gear for Powell Evans, Philadelphia, Pa. Filed May 10, 1906. Serial No. 316,086. Renewed November 4, 1908.

923,643. Spring Wheel.—Theodore W. Gratz, Jr., Olean, N. Y. Filed January 23, 1907.

923,707. Spring Wheel.—James E. Rielly, New-

ark, N. J. Filed September 21, 1907.
923,733. Puncture Proof Tire.—Eugene J. C. Timerman, Syracuse, N. Y., assignor of one-third to Louis C. Crowell, Syracuse, N. Y. Filed July 31, 1908.

923,764. Vehicle Suspension.—Frederick D. Brown and Walter D. Whitney, Minneapolis, Minn. Filed March 16, 1908.

923,765. Spring Suspension.—Alanson P. Brush, Detroit, Mich. Filed October 6, 1906.

923.787. Variable Drive Mechanism. B. Gray, Jacksonville, Ill.; Bartlett S. Gray executor of said Stephen B. Gray, deceased.

April 6, 1905. 923,788. Variable Speed Mechanism.—Stephen B. Gray, Jacksonville, Ill.; Bartlett S. Gray executor of said Stephen B. Gray, deceased. Filed May 5. 1006.

Motor Vehicle,-Stephen B. Gray. 923,789. Jacksonville, Ill.; Bartlett S. Gray executor of said Stephen B. Gray, deceased. Filed February 24, 1908.

Reissue 12,966. Power Transmitting Mechanism for Automobiles.—Louis P. Mooers, Geneva, Ohio, assignor to the Peerless Motor Car Co., Cleveland, Ohio, a corporation of West Virginia. Filed April 13, 1909. Serial No. 489,744. Original No. 832,991; dated October 9, 1906.

### Patents Issued June 8, 1909.

923,825. Automobile Turntable.-Charles K. Elmer, St. Paul, Minn. Filed October 29, 1908. 823,849. Mud Guard.—Bryan L. Jonse, Highbury, London, England. Filed February 3, 1908. 923,858. Cushioning Device.-Frederick O. Kilgore, Minneapolis, Minn., assignor to Kilgore

Manufacturing Company, Oldtown, Me., a corporation of Maine. Filed December 22, 1905. 923,881. Hydro-pneumatic Wheel.-Henri Oudi-

not and Charles Putois, Paris, France. Filed June 15, 1008. 923,900. Friction Clutch.-Joe E. Shearer, San

Francisco, Cal., assignor to California Clutch Company, San Francisco, Cal., a corporation of California. Filed July 25, 1908.

923,019. Vehicle Hub.—William R. Wilson, Cin-

cinnati, Ohio. Filed March 5, 1908.

923,938. Clutch Mechanism for Motor Vehicles. -Robert H. Bowman, Canon City, Col. Original application filed October 30, 1907, Serial No. 399,-908. Divided and this application filed May 5, 1008.

923,956. Oil Clutch and Speed Regulator.— Hugo Dotzer, Seattle, Wash. Filed December 31,

924,036. Spring Wheel.—Richard H. Burgess, Mullin, Tex. Filed September 30, 1907.

924,044. Apparatus for Injecting Fuel into Internal Combustion Motors .- Fritz Dürr, Frankforton-the-Main, Germany. Filed December 17, 1907.
924,061. Running Gear for Automobiles.—Herman J. Hass, Buffalo, N. Y., assignor to E. R. Thomas Motor Company, Buffalo, N. Y. Filed April 14, 1906.

924,102. Pneumatic Tire.-Frederick H. Perry, Beverly, Mass. Filed December 30, 1908.

924,139. Vehicle Wheel.—Frank Bradley and Frank H. Fairchild, Detroit, Mich., assignors of one-third to Charles C. Bradley, Mount Clemens, Mich. Filed March 26, 1906.

924,148. Folding Box Seat.—George E. De Vore, Lansing, Mich. Filed December 16, 1908. 924,179. Shock Absorber.—Henry Muchihausen. Jr., and Johannes Thomsen, Chicago, Ill. Filed August 17, 1908.

924,182. Automobile Scenic Railroad.—Asa G. Neville, Wellsburg, W. Va. Filed December 15, 1908.

924,186. Tire Casing .- John F. Palmer, Chicago, Ill. Filed October 14, 1907.

924,187. Universal Joint Coupling.-Friedrich Panse, Essen-on-the-Ruhr, Germany, assignor to Fried. Krupp Aktiengesellschaft, Essen-on-the-Ruhr, Germany. Filed June 27, 1907. 924,188. Holder for Lap Robes.—Charles B.

Phillips, Red Wing, Minn. Filed October 9, 1908. 924,513. Gas Lighting System for Automobiles. -Ernest Timmerhoff, Warsaw, Ind. Filed February 8, 1000.

Carburetor .- Alfred C. Stewart, Los 924,200. Angeles, Cal. Filed November 25, 1907.

Tire Casing .- John F. Palmer, Chi-924,267. Tire Casing.—John cago, Ill. Filed January 2, 1906.

Tire Casing.-John F. Palmer, Chi-924,268.

cago, Ill. Filed January 2, 1906. 924,323. Transmission Gear for Propeller Shafts and the Like.—Paul Daimler, Untertürkbeim, near Stuttgart, Germany, assignor to Daimler-Motoren-Gesellschaft, Stuttgart, Germany. Filed November 12, 1908.

924,334. Vehicle Wheel .- James R. Minneapolis, Minn., assignor to Fouch Disc Wheel Company, Minneapolis, Minn., a corporation of Minnesota. Filed February 9, 1905.

924,571. Tire Casing.—John F. cago, Ill. Filed October 12, 1905. Tire Casing.-John F. Palmer, Chi-

924,572. Pneumatic Tire.-John F. Palmer, Chicago, Ill. Filed March 23, 1908.

924,614. Vehicle Wheel.—Louis A. Hill, Wash-gton, D. C., assignor to American Resilient ington. Wheel Company, a corporation of Delaware. Filed April 3, 1908.

924,621. Cushioned Vehicle Wheel.—William C. McCarty, Birmingham, Ala. Filed December

### Patents Issued June 15, 1909.

924,640. Explosion Engine.-Harry M. Cramer, Lansing, Mich. Filed April 20, 1908.

024.673. Carburetor.—James B. Knickerbocker. Indianapolis, Ind. Filed November 21, 1907.

924,806. Anti-Skidding Attachment for Wheel Tires.—George A. Lyon, Philadelphia, Pa. Filed March 18, 1907.

924,817. Shock Absorber,-Charles H. Newton, Torrington, Conn. Filed October 27, 1906.
924,820. Automobile Truck.—Herbert L. Par-

rish, Benton Harbor, Mich. Filed February 28, 1908.

924.812. Pneumatic Tire.-Daniel McArthur. Jersey City, N. J. Filed April 15, 1908. 924,847. Variable Speed and Reversing Gear-

-Arthur C. G. Smith, London, and Edward H. J. C. Gillett, Hounslow, England. Filed August 5, 1908.

Elastic Vehicle Tire .- Charles Motz, 925,937. Akron, Ohio. Filed July 31, 1908.

925,969. Tire Patch.—John A. Wheeler, On-away, Mich. Filed March 30, 1909.

925,973. Carburetor.-Alexander Winton and Harold B. Anderson, Cleveland, Ohio, assignors to the Winton Motor Carriage Co., Cleveland,

Ohio. Filed April 9, 1907.
926,012. Elastic Vehicle Tire.—Charles A.
Motz, Akron, Ohio. Filed September 26, 1906. 926,039. Carburetor.—Edward F. Warren, De troit, Mich., assignor of one-half to Maurice E. Garrett, Wayne County, Mich. Filed July 22, 1008.

926,066. Multiple Contact Timer .- Edwin S. Lincoln, Brookline, Mass., assignor to Electric Goods Manufacturing Co., Boston, Ma corporation of Maine. Filed May 5, 1908. Mass.,

### Patents Issued June 29, 1909.

926,104. Tire Protector.—Frank H. Davis, Chicago, Ill. Filed December 2, 1907.

926,118. Folding or Collapsible Top for Automobiles.—Herman M. Hoelscher, Chicago, Ill. Filed November 5, 1908. 926,141. Clutch.—Charles Schmidt, Cleveland,

Ohio, assignor to the Peerless Motor Car Company, Cleveland, Ohio, a corporation of West Vir-

ginia. Filed January 15, 1906. 926,147. Turntable.—Albertus O. Slentz, Canton, Ohio, assignor of one-half to the Canton Foundry and Machine Company, Canton, Ohio, a corporation of Ohio. Filed April 23, 1909.

926,176. Spring Buckle for Securing Springs Axles .- Paul Daimler, Unterturkheim, Germany. Filed October 25, 1906. 926,186. Automobile Advertising Device.—

George Heales and Walter R. Neall, Baltimore, Md. Filed April 20, 1908.

926,195. Trunk.—Isidore S. Kallis, New York, and Joseph Berg, Brooklyn, N. Y. Filed November 2, 1908.

926,290. Motor Vehicle.—Louis S. Ross, Newton, Mass. Filed July 24, 1906.

926,296. Vehicle Wheel Rim.-Edwin C. Shaw, Akron, Ohio, assignor to the B. F. Goodrich Company, Akron, Ohio, a corporation of Ohio. Filed January 6, 1906.

926,313. Traction Wheel.—Chester T. Bangs, Chicago, Ill. Filed December 10, 1906. Serial No. 347,016. Renewed January 9, 1909.

926,330. Electric Ignition Device.-Theodore Hubert, New York, N. Y., assignor to Charles F. Splitdorf, New York, N. Y. Filed April 4, 1906. 926,347. Pneumatic Tire.—Maurice Marcille,

Paris, France. Filed December 29, 1906. 926,390. Motorcycle.—John David, Geneva, Switzerland, assignor to J. David & Cie., Geneva, Switzerland. Filed October 3, 1906.

926,411. Motor Vehicle.—Henry P. Haushalter, Milwaukee, Wis. Filed July 22, 1908.

Tire .- John C. Raymond, New York, 926,439. N. Y. Filed October 5, 1908.

926,533.. Carburetor.-Alexander Winton and

Harold B. Anderson, Cleveland, Ohio, assignors to the Winton Motor Carriage Company, Cleveland,

Ohio. Filed March 9, 1907.
926,540. Engine.—Henrik E. B. Blomgren,
Palmyra, N. J. Filed January 27, 1906.

926,557. Drive Gearing.-Norman Frye, Lin-

coln, Kan. Filed October 26, 1908. 926,598. Carburetor.—William L. Perry, Scrana. Filed December 27, 1907.

Vehicle Wheel.—Guy C. 926,650. Berwyn, Ill., assignor to the Perfection Emergency Company, Chicago, Ill., a corporation of Il-

linois. Filed October 29, 1908.
926,685. Upthrow Cushion Spring for Vehicles. -Charles L. Thomas, Canisteo, N. Y., assignor of one-half to Frank Caulkings, Canisteo, N. Y. Filed March 3, 1908.

926,695. Vulcanizing Apparatus for Tire Tubes Covers.-William R. S. Frost, London, Eng-

land. Filed February 6, 1909.
926,701. Steam Generator Flue.—Charles F. 926,701. Steam Generator Flue.—Charles a. Jenkins, Washington, D. C., assignor, by direct and mesne assignments, to General Electric Company, a corporation of New York. Original application filed August 27, 1901. Serial No. 73,471. Divided and this application filed January 2, 1907.

### New Incorporations.

Auto Parts Co., Chicago, Ill.-Capital stock, \$50,000. Incorporators, Bert Symons, Archie Symons and Frank Keown.

Piper Lowry Auto Co., San Antonio, Tex.-Capital stock, \$15,000. Incorporators, F. A. Piper, Sr.; W. E. Lowry and P. H. Long.

The Farmersville Auto Co., Farmersville, Tex.—

Capital stock, \$2,400. Incorporators, E. W. Stewart, J. B. Honaker, A. F. Yeager and others.

The Queen City Auto Livery Co., Buffalo, N. Y. —Capital stock, \$25,000. Incorporatora, Chas. V. Roty, Harry C. Shufeldt and Wm. J. Hickey.

Mechanical Tire Co., Jersey City, N. J.—To manufacture rubber tires, etc. Capital stock, \$500. 000. Incorporators, H. C. Coughlan, S. A. Anderson, C. B. Leggett.

The Chalmers-Detroit Motor Car Co., of Dayton, Ohio.—Capital stock, \$5,000. Incorporators, Ernest Ooley, Joseph H. Ooley, Albert Emanuel, Benjamin J. Ooley and Geo. W. Schaeffer.

Waddell & Emerson Stage Co., North Creek, N. Y.—Capital stock, \$12,000. Incorporators, R. Waddell and Robert Waddell, of North Creek, and James A., Margaret and Louis M. Emerson, of Warrensburgh.

The Auto Car Service Co. of New Jersey, Camden, N. J.-Objects, to manufacture, sell and operate automobiles and other vehicles, and to establish a public garage. Capital stock, \$10,000. Incorporators, E. A. Fitts, David S. Ludlum, John

### Trade Personals.

Wm. C. Longstreth has severed his connection with the Longstreth Motor Car Co., Maxwell dealers in Philadelphia, and plans to secure the Philadelphia agency for a number of different makes for the coming season.

Chapin, treasurer and general manager of the Chalmers-Detroit Motor Co., will sail for Europe the middle of this month. He will visit England, France, Germany and Italy, attend a number of automobile events, and return in September.

A. W. Hall, formerly of Cleveland, Ohio, has assumed the management of the Plymouth Truck Co., Plymouth, Ohio. He has withdrawn from the firm of Hall Brothers, 1613 Euclid avenue, Cleveland, agents for the Plymouth truck and the Cartercar, which business will be continued by his brother, V. R. Hall, under the firm name of the V. R. Hall Automobile Co.

R. Harry Croninger, general manager of the Penasylvania Auto-Motor Co., Bryn Mawr, Pa., has resigned, and has been succeeded by Dr. Caspar Miller, a large stockholder in the company. It is reported that Croninger, who was formerly sales manager of the Dayton Motor Car Co., will go to the Pacific Coast. He returned only recently from a business trip to that section of the country.

NUMBER 2

#### The Vaporizing Function of the Carburetor.

By ALBERT L. CLOUGH.

The most pressing question in the automobile industry at the present time is that of carburation, and the most urgent feature of that question is to be found in the vaporization phase of the problem. The proportioning function is fairly well performed by many carburetors and very well by some, but perfectly, perhaps, by none. However, there is always manual regulation to fall back upon to make good the shortcomings of carburetor automaticity, and provisions for such supplementary manual control are being provided quite generally of late. But if a carburetor fails to carburate, that is, if it fails to add to the entering air a due proportion of fuel in vapor form, it falls short of its purpose.

VAPORIZATION MUST PRECEDE COMBUSTION.

An internal combustion engine can be operated without any carburetor per se. A measured quantity of fuel can be squirted upon the inlet valve during each suction stroke or introduced into the combustion space through a special injection nozzle, This practice is common in stationary work, where low rotary speeds prevail. The valve and the port walls and other adjacent surfaces swept by the entering charge constitute the vaporizing surfaces under these circumstances, and they have the advantage over the evaporating surfaces of many carburetors of being in a constantly heated condition. During the compression period, in such an engine, high temperatures are reached on account of the high pressure carried, and vaporization is thus completed. Such engines run at low speeds, and the time allowed for the heat interchanges resulting in vaporization (and vaporization is solely a phenomenon of heat transference) is several times that available in a vehicle motor. When less than the requisite time is allowed for the cycle, the extent and temperature of the vaporizing surfaces remaining the same, the evaporation of the fuel will be incomplete at the end of the compression stroke. Liquid fuel cannot burn as such, and fuels can only unite with oxygen when in the aeriform condition. Whatever fuel remains in the liquid condition up to the beginning of exhaust is ejected unburned, and all fuel failing of vaporization up to the end of the compression stroke is very inefficiently utilized. To make an engine operate efficiently at high speed, when fed by the injection system, an extent of highly heated surface must be exposed to the fuel and air beyond that possible of provision in practice.

GAS ENGINE MIXTURES IDEAL.

An ideal gasoline carburetor should deliver the fuel mixture in as completely aeriform a condition, that is, as free from entrained liquid hydrocarbon, as does the mixing valve of a gas engine; but the only type of gasoline carburetor which approaches measurably near this ideal in this respect is the surface carburetor, in which the required air circulates over a very large expanse of gasoline wetted surface in the presence of an adequate available heat supply. A fuel vapor practically free from admixture of entrained liquid can be obtained from one of these vaporizers. The average carburetor of the prevailing float feed spraying type only imperfectly performs the work which it is designed to do. It occupies a position between a liquid fuel injecting device and a vaporizing device of ideal characteristics. The charge which it delivers to the intake piping consists, as a rule, of a rather weak mixture of gasoline vapor and air, in which are carried small drops of gasoline, in a condition very similar to that in which water exists in priming in steam. In the inlet piping this mixture may be modified either by a reduction of the entrained globules of gasoline and a consequent increase in richness of the aeriform portion of the charge, or less probably by a further increase in the proportion of condensed gasoline. In either case, except under very unusually favorable circumstances, some liquid gasoline reaches the cylinders, and is utilized, if at all, as is the fuel supplied by the injection system spoken of above. Its partial evaporation in the cylinder serves to enrich the aeriform portion of the charge furnished by the carburetor. but it is usually only partially volatized, and whatever portion escapes volatilization is lost, and much worse than lost, as cylinder incrustations and an offensive exhaust result from it.

THE ORDINARY CARBURETOR.

The ordinary carburetor itself acts mainly as a proportioning and pulverizing device, and the walls of the combustion space act to quite an extent as a surface carburetor. The intervening piping acts also as a surface carburetor to a greater or less extent. If the mixture passages intervening between the jet of the carburetor be possessed of a sufficiently energetic surface carburetor action to vaporize all the liquid hydrocarbon within them before it leaves them, perfect carburation, so far as the volatilization of the fuel is concerned, will result. It may

become necessary before a solution of the problem of complete vaporization outside the cylinder is arrived at to interpose between the jet carburetor of the accepted type and the inlet ports a vaporizing apparatus, constituting a true surface carburetor, possessing the regular characteristics of large exposed area, somewhat tortuous passages in order to bring all the liquid against these surfaces and a free heat supply to these surfaces.

PREHEATING THE GASOLINE.

A volatile fluid like gasoline, when it escapes in a finely subdivided and in a heated condition from a region of higher to a region of lower pressure, passes very rapidly into vapor, in exactly the same manner as the hot water in a boiler passes into steam when the blow-off is opened, and if gasoline could be furnished the air under these conditions the difficulties of full vaporization would largely be eliminated. The extent to which the gasoline in a regular carburetor can advantageously be heated is, however, extremely limited, for if its temperature is greatly raised vaporization will take place in the passage of the jet, vapor will flow through it instead of liquid, and its capacity for passing fuel will fall to a small value, and only an unworkably weak charge will result. Heating the float chamber by means of a jacket up to the safe limit as defined above materially increases the tendency toward the gasification of the fuel, especially as the gasoline when leaving the jet and entering the float chamber meets with a pressure slightly below atmosphere. The denser the fuel used the higher the temperature of the float chamber may be carried

One can conceive of a carburetor gasoline bowl in which the liquid is kept at a temperature representing enough heat fully to vaporize it at the pressure existing in the spray chamber, into which it is to escape, and under a slight pressure. The jet orifice might be closed by a spring seated ball acting as a check valve, which might be unseated to allow the flow of fuel by a pressure impulse derived from the exhaust or in some equivalent manner.

COMPARISON OF METHODS.

There is very little doubt that the supplying to the liquid fuel directly of sufficient heat to vaporize it is a far preferable method to that of depending upon the absorption of the requisite heat by contact of the fuel with hot surfaces after entering the vaporizing chamber. It has been repeatedly pointed out that preheating of the air for the mixture is a less desirable

method of supplying the necessary heat than that of heating the liquid fuel, for the specific heat of air and its conductivity are low and the heat required for the vaporization of a fuel globule is applied externally to that globule by the warmed air.

In the case of a carburetor having a hot jacket about its vaporizing chamber there is constantly a film of gasoline adhering to and taking its heat of vaporization from the warm walls, which film is constantly being renewed by the breaking against the walls of the globules from the jet. As the liquid laden air in the vaporizing chamber is in violent motion the chances of the liquid particles meeting the warm walls are good, and the vaporizing effect is good, so far as it goes.

#### UNJACKETED FUEL SUPPLY SYSTEMS.

It sometimes seems remarkable how engines run as well as they do, especially during cold weather, from carburetors and inlet pipes which are entirely unjacketed and not even provided with a hot air supply. There are thousands of engines thus running, however, but it is hardly to be expected that they are operating very efficiently. Practically all the heat to vaporize the fuel (outside of the engine itself) is derived from the air. The heat in the entering air and the heat of the outside air entering by conduction through the metal of the vaporizing chamber, the mixture pipe and the manifold, constitute the entire thermal supply, with the exception of the small amount of heat which is conducted by the manifold from the engine. That the call for heat is greater than the available supply is shown by the coldness of the carburctor and its piping. Where no artificial heat supply is provided, and the natural heat of the air is depended upon, it seems strange that thin copper pipes provided externally with metal fins are not used. Such a construction would favor the transference of the heat of the outside air into the contents of the piping. The employment of piping of circular section is unfavorable to the entrance of heat through its walls, either from the outside air or from a jacket, as its wall surface is a minimum as compared with its cross-section. A pipe of flattened section exposes a large wall surface for the entrance of heat and a large internal surface, which will carry an extensive film of liquid fuel, and into contact with which the entrained gasoline will be more likely to come than in the case of a circular sectioned passage.

#### IMPARTING HEAT TO INLET PIPES.

In order to increase the external temperature of the inlet piping, and hence to increase the transfer of heat into the contents thereof, and thereby to augment the surface evaporation, a number of expedients are occasionally employed. The inlet manifolds of a few foreign vehicle engines are cast integrally with their exhaust manifolds, the inlet manifold being within, and therefore jacketed by the exhaust gases. A large heat supply is thus available after

the engine is in action to effect the vaporization of liquid fuel which survives as such up to this portion of the intake system. There would seem to be a possibility of the heat supply being excessive under these circumstances which might lead to a preheating of the charge beyond the point of complete evaporization of the contained fuel, but this danger may be regarded as less than that due to a deficit of heat. The combination of the two manifolds in a single casting calls for rather complicated foundry work, and one would think for special expansion joint provisions. An inlet manifold surrounded with a jacket through which the circulating water flows has been used on a few engines, and should greatly increase the heat supply available for the evaporation of the film of gasoline carried by the walls of the manifold. The same effect is produced by the cored out inlet passages in block motors, which are enveloped by the cylinder jackets, and, in a slight degree, in the case of the siamezed intake passages found in engines with twin cast cylinders.

#### WATER JACKETING INEFFECTIVE AT START.

Heat from the circulating water only becomes available in its fullness after the motor has been run for a length of time sufficient to bring the temperature to the normal operative value. Strictly speaking, the temperature of the jacket water should increase with the instantaneous rate of fuel consumption, and in a way this is automatically brought about; but there is quite a time lag between a sudden call for increased fuel consumption and the rise in jacket water temperature which this brings about

Heat supplied from the exhaust is fully available as soon as the motor begins to run, and the exhaust temperature varies with the rate of fuel consumption without any time lag. between the two. Jacketing with the exhaust has the objection, however, that water, excess lubricating oil and soot carried by the escaping gases are likely to foul and even to clog any small passages which may exist in the system. Exhaust jacketed carburetor bowls have been tried and discarded by a number of makers upon this account.

In the case of one American vehicle motor of the block type the riser or vertical pipe connecting the carburetor to the single intake connection is water jacketed. Such a construction is perhaps better than that in which the application of heat is delayed until the manifold is reached, as the earlier the heat is applied the greater the chance of full evaporation being effected.

#### VAPORIZING TUBE CARBURETOR.

In the vaporizing tube carburetor, which was treated very ably by Chester S. Ricker in the March 31, 1909, number of The Horseless Age, heat is applied to the walls of a vertical tube through which a very much overrich mixture is passing, the jet being located in the lower end of this tube. Heat must be applied under these circumstances much more effectively than if it

were acting upon a mixture containing the full proportion of air. One may imagine the fuel globules closer together, and with less insulating air between them, in this dense mixture than in the case of a mixture containing the full amount of air. The main object is, of course, to transfer heat to the globules and not to the air. More globules per unit of time may be expected to come into contact with the hot walls in the case of a mixture densely loaded with such globules than in one relatively sparsely loaded with them. Applying heat to an overrich mixture like this is approaching nearer to applying heat to the liquid fuel in bulk.

#### HEATER TUBES IN 1ET CHAMBER.

The various methods heretofore described for applying vaporizing heat have all consisted in merely warming the wall of a passage through which the mixture is passing. In an article by Perry Okey on page 589 of Vol. 21 of this journal, is shown a pipe leading from the jet chamber of the carburetor which is full of staggered tubes forming water legs, which are full of warm circulating water, and against which the entrained fuel globules strike in their passage and upon which they evaporate. The warm surface is so much enlarged by this arrangement as to constitute it a distinct improvement over the ordinary jacketed pipe. This article is well worth a careful rereading by all persons interested in the carburation problem, for the vaporization phase of the question could hardly be better set forth than it is there. As Mr. Okey says, the device is a surface vaporizer through which the mixture from a proportioning carburetor passes, and the present writer believes that this device is quite typical of the sort of thing that will have to be generally adopted in practice in this day of fuel of relatively low volatility, of greater care in the matter of fuel economy and when carbonization is a much dreaded evil.

It should be remarked, perhaps, that a device of this kind ought to be so arranged as to prove a most effective "trap" for liquid fuel as well as highly effective as a vaporizer. The prevention of any liquid globules from reaching the cylinders is very important. Surfaces covered with some fabric or other fibrous material entrap liquid globules much more certainly than do smooth metallic surfaces, and fibrous bodies offer an immense amount of surface in proportion to the space they occupy. This fact was taken advantage of in the old forms of surface carburetor. A fabric moistened by a volatile liquid gives off vapor most freely, and will not part with the liquid, as such, unless a very great excess of liquid has been absorbed by it. Wire gauze possesses in a slight degree this property of fibrous bodies.

It would not be strange if fibrous or absorbent materials, arranged upon heated baffling plates, should be used to effect the evaporation of entrained liquid fuels. A device of this kind must not be so con-

tracted as to offer a material throttling effect, and on the other hand it must not be unduly bulky.

#### SURFACE VERSUS TEMPERATURE.

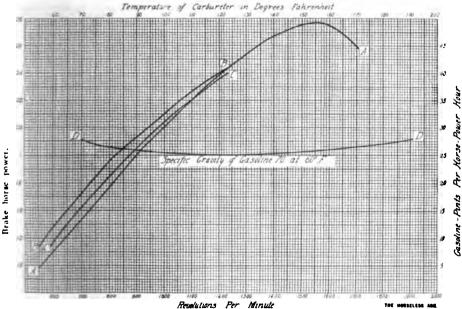

A large amount of evaporating surface in the path of the fuel globules maintained at a very moderate temperature is far preferable to a smaller surface kept at a high temperature. The temperature of the charge entering the cylinders can never rise above the temperature of the heating surfaces, and, in practice, will be very much lower, so that when large, moderately warmed surfaces are used the evaporation even of dense fuels can be effected without serious danger of preheating.

# Some Tests of an Automobile Motor.

The following tests were conducted with a four cycle, four cylinder, water cooled gasoline motor with a bore of 100 mm. and a stroke of 112 mm., with valves on opposite sides, spark plugs located in the caps over the inlet valves, and magneto ignition. The crank shaft revolved in babbitt bearings and the cam shafts in bronze bearings. The upper ends of the connecting rods had hardened steel bushings operating on hardened steel pins. The lower ends had babbitt bearings. The lubrication was by splash, sufficient oil being fed to produce a slightly smoky exhaust. The compression of the motor when cold was 76 pounds. The water jacketed carburetor was fitted with three nozzles, which automatically came into operation successively as the throttle was opened.

The object of the first series of tests was to determine the maximum horse power which the motor would deliver constantly to a Prony brake. The series comprised four tests, extending over one hour each, and the results are shown by curve A, Fig. I, which clearly shows the speed torque characteristics of the motor. This indicates that at 295 r. p. m. the motor delivered 81/2 horse power, and that the power increased rapidly up to 1,000 r. p. m., when there was a slight change in the rate of increase until the speed reached 1,550 r. p. m., when the power began to decrease very rapidly. The rate of decrease in power delivered from 1,550 to 1,710 r. p. m. was more rapid than the rate of increase from 1,350 to 1,550 r. p. m. The temperature of the outgoing cooling water throughout this series of tests averaged 182° Fahr.

The second series of tests were conducted for the purpose of determining the relation between the horse power delivered by the motor at various engine speeds and the temperature of the water in the jackets. The results of these tests are shown by curves B and C. Curve B shows the relation between the speed in revolutions per minute and the brake horse power when the jackets were practically cold, or at a temperature of 79° Fahr. Curve C shows the relation with the temperature of the water jackets at 167° Fahr. It will be noted that with cold jackets 12.8 horse power was delivered at 600 r. p. m., and with warm jackets 11.7 horse power was delivered at the same speed. Likewise at 900 r. p. m. 19.22 horse power was delivered with cold jackets and 18.6 horse power with warm jackets. This shows a slight decrease in the difference of the horse powers at the two speeds. At 1,200 r. p. m. 24.25 horse power was delivered with cold jackets, and 24 horse power with warm jackets; a still greater decrease in the differences. The room temperature throughout this series of tests was 57° Fahr., and the arrangement

A.A. Speed-Norse Power, Maximum Continuous'

B.B. Speed-Horse Power with cold jackets

C.C. Speed Norse-Power with warm jackets

FIG. 1.—CHARACTERISTICS OF A GASOLINE MOTOR.

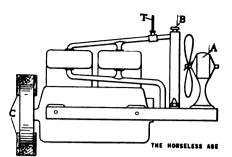

Fig. 2.—Arrangement of Apparatus for Testing Motor.

A, electric fan, the speed of which can be controlled by a rheostat; B, radiator kept at a fixed temperature by the fan; T, thermometer, inserted in water outlet manifold; C, blocks of Prony brake, cooled and lubricated by soapy water.

of the apparatus is shown by Fig. 2. The temperature of the cooling water was kept nearly constant by means of the large electric fan A, which delivered air to the radiator B. The speed of the fan could be varied by means of a rheostat inserted in its circuit, and during the tests with cold jackets cooling was assisted by a small stream of cold water from the city mains, which was fed to the radiator and caused it to overflow continuously. The temperature of 167° Fahr, was decided upon after several tests with cars operating under ordinary road conditions, and may be taken as the average temperature of the cooling water as it leaves the engine under ordinary conditions.

The third series of tests were made to determine the relation between gasoline consumption and the temperature of the carburetor water jacket. The motor was operated at 1,520 r. p. m. and delivered an average of 26.7 horse power for two hours. The result of these tests is shown by curve D. It will be noted that when the temperature of the carburetor jacket was increased from 70° to 120° Fahr. the gasoline consumption decreased very rapidly, and when the temperature was increased above 130° the consumption increased, but not quite as rapidly as it decreased in raising the temperature from 70° to 120°, thus showing that for economy the carburetor under test should be kept at a temperature of from 120° to 140° Fahr.

The Vienna Chamber of Commerce has donated sums of 200 crowns and 100 crowns, respectively, which are to be offered in the form of scholarship prizes in connection with the next course in automobile repair work for Alpine blacksmiths and locksmiths conducted under the auspices of the Austrian Automobile Technical Association in the blacksmith and locksmith shops of the Imperial Trade Promotion Bureau in Vienna. One such course was conducted this year, and proved quite successful. A number of firms in the industry sent some of their foremen to lecture at these courses, and also furnished material for illustrating the lectures.

#### The Garage Business at Seaside Resorts.

By Joseph A. Anglada.

The manager of a garage at a seaside resort is confronted with problems entirely different from those of a garage in a city. In a city there is always some garage business, irrespective of the season of the year; even in winter cars are on storage, and generally there are one or two jobs in the shop. In the spring owners have their cars put in shape for the driving season, and during this season the business generally runs along steadily until cold weather sets in, when most owners put their cars in storage. Occasionally, on a very warm evening, or on a Sunday or holiday afternoon, there may be a sudden increase in the demand for supplies, but the "rush" is generally of such short duration that the regular staff of employees is capable of handling it.

With a seaside garage, however, matters are entirely different. The season begins in May and ends in September, as far as profitable business is concerned, and unless there are a number of resident owners or the garage has a few regular patrons who motor to the seaside on pleasant winter days, it is doubtful whether it pays to keep the garage open for business the year round. In the busy season a seaside garage, as a rule, does very little business in the morning, but from about five in the evening until midnight cars come in large numbers, and owners, as a rule, put their cars under cover, where they will be guarded against theft, in preference to leaving them alongside of the curb at the mercy of the small boy and the mischievous individual. On Saturday cars arrive earlier, especially if the resort boasts a fine bathing beach, and in many cases they leave at an early hour, only to be replaced by large numbers of cars whose occupants spend the evening at the resort. On holidays and Sundays cars begin to arrive as early as 9 a. m., and along about 2 o'clock in the afternoon the influx is at its maximum. This transient trade consists mostly of owners who live from five to twenty miles from the resort and who drive to the coast to enjoy the sea breezes and have dinner before driving home. These owners store their cars regularly in public garages near their homes, and in a few cases in their private garages. They purchase their supplies and accessories from these garages or from regular supply and accessories houses, so that the seaside garage keeper receives but little call for supplies, and practically none for accessories, unless, as previously stated, there are local owners who store their cars at his garage. The rates for owners generally vary from \$20 to \$30 per menth, and include storage, washing and polishing. The rates for transients vary with different localities, but, as a rule, a charge of 25 cents for six hours or any part thereof is made for storage on all days except Saturdays, Sundays and holisimilar period.

#### REPAIR FACILITIES.

The nature of the repairs which a seaside garage is called upon to make does not necessitate an extensive tool equipment, it being found advisable to make arrangements with a good shop in a nearby section where repairs may be sent, and in many instances seaside garages are operated as auxiliary to such shops or to garages in the city. A well equipped emergency car should, however, form part of the equipment of the garage, so that roadside repairs may be made, and, if necessary, the disabled car towed where it can be repaired. The emergency car should be fitted with compartments for carrying a few inner tubes, shoes, blow-out patches, chains, a spare wheel equipment which can be secured to the hub of a broken wheel, spring repair clamps, a set of dry batteries, a single unit spark coil, some high tension and low tension ignition cable, spark plugs of the various sizes, a box of odds and ends, including various sizes of bolts, nuts and pins, a coil of soft iron wire and a few rolls of wide rubber tape for temporarily repairing broken pipes, etc. A complete set of the usual automobile wrenches, screwdrivers, etc., in addition to two good jacks, should also be included in the equipment, as well as a tire pump operated by the motor of the car. A sealed five gallon can of gasoline in a protecting crate, three one gallon cans of engine oil and a small can of grease should also always be on the car.

The shop equipment of such a garage as we are considering should comprise a 16 inch lathe with screw cutting attachment for turning pins, etc, and for straightening bent shafts; a sensitive drill press with various sizes of drills and taps; a small forge and anvil used principally for straightening bent parts, and a complete soldering outfit for repairing radiator leaks,

#### PROTECTION AGAINST STORMS.

The building in which the garage is housed should cost as little as is consistent with good appearance and thorough protection against storms, because on the occasion of a sudden storm the seaside garage finds the protection which it offers its greatest advertisement. The interior should be well lighted by day and night, and, if possible, there should be an entrance at one end and an exit at the opposite end or side of the building. Otherwise, if but a single doorway is possible, it should be wide enough to permit a car to enter while another is coming out. The runway leading to the building should have a gradual slope, and the street in front of the building should be well drained, because a muddy street, such as is often found in front of resort garages, creates a bad impression which certainly does not make the place popular. The floor of the garage should be far enough above the level of the surrounding property to prevent the possibility of water entering in the

days, when the charge is 50 cents for a event of a heavy rain, such as frequently occurs during the summer months. Gasoline should be stored in a tank, buried some distance from the building, and the pump for drawing gasoline from the tank should be located in a small fireproof house, which should be well ventilated.

> In a number of garages of this class. when a car is placed in its charge, the driver is given a numbered cardboard tag, a duplicate of which is secured to the car. which is only surrendered to the possessor of the tag. Others use brass checks, resembling baggage checks, instead of the cardboard tags. At some of the garages which use cardboard tags the time of arrival of the car is stamped upon the tag in order to prevent disputes. This elaboration is, however, hardly necessary considering the short period of storage and the small sums charged.

Italian Imports and Exports.

The Italian Minister of Commerce has just published the statistics of imports and exports during the year 1908, from which we reproduce herewith the figures relating to Italy's foreign automobile trade. The imports of motor trucks, pleasure vehicles and motorcycles during the year were valued at 4,877,522 lire (1 lire is equal to about 20 cents), which represents a reduction of 4,015,013 lire, or 45.2 per cent. from the figures for 1007. The exports of automobiles, on the other hand, attained the very respectable total of 28-683,575 lire, an increase of 8,233,815 lire, or 40.2 per cent. over the figures for 1907. As regards the importation of pleasure vehicles in 1906, 931, valued at 9,957,316 lire. were imported; in 1907, 725, valued at 8,-266,335 lire, and in 1908 only 348, valued at 4,354,492 lire. The movement in the exports has been the exact opposite of that shown by the imports. During 1906 the Italian industry exported 829 pleasure vehicles, valued at 11,847,700 lire; in 1907. 1,283 vehicles, valued at 20,185,310 lire, and in 1908, 1,629 vehicles, valued at 28,-236,745 lire.

The entire increase in exports was in pleasure vehicles. (In fact, only for 428,130 lire Italian trucks were exported, and for 18.700 lire Italian motorcycles.) The French exports to Italy have diminished during the past several years. Thus in 1906 France exported 706 cars to Italy, in 1907 473 and in 1908 only 238. On the other hand. France also buys fewer Italian vehicles every year. Thus in 1906 464 Italian cars were imported into France, in 1907 353. and in 1908 only 275. The bulk of the increase in the Italian exports is taken by England. In 1906 only two Italian cars were imported into the United Kingdom, in 1907 125 and in 1908 388.

The Argentine Republic is said to be the greatest horse using country in the world. and the only country in which there are more horses than people, there being 112 horses to 110 inhabitants.

#### THE HORSELESS AGE

9-15 Murray St., New York.

#### Crude Rubber Prices Soaring Again.

The era of low priced pneumatic tires, which began last September, or somewhat earlier if we include the cut price period, promises to come to an early end, for presumably changes in tire prices will not lag as far behind changes in rubber prices in a rising market as they did in the falling market. The prices of the best grades of crude rubber used in tire manufacture have recently risen to unprecedented figures. This rapid rise is as hard to explain as the preceding sharp decline. These two price movements were certainly not the result of sudden fluctuations in the demand for rubber for automobile tires. While in this country the automobile industry is unusually active this season, depression reigns in the European industries, in England as well as on the Continent, and the aggregate number of cars produced this year will not greatly exceed that of last year and will show only a normal development of the industry. It is, of course, possible that increasing activity in other industries after the world-wide depression has resulted in an increased demand for Para rubber. What seems more likely, however, is that

the rubber producing states have found ways and means of restricting the output. Indeed, the official statistics, published in our last issue, show that actually less rubber was shipped from Para during the fiscal year 1908-09 than during the year 1906-07. The latter year showed a very material increase in the amount of rubber shipped from Para over the previous year, and this sharp increase in production seems to have precipitated the drop in prices of several years ago.

In this connection it must be borne in mind that rubber is a material for which there are no substitutes, and its consumption is not affected to any extent by fluctuations in price. No one will delay the purchase of a motor car or use his car less because rubber tires are temporarily unusually high in price, because the tires constitute only a fraction of the cost of a car. The cost of the crude rubber, moreover, represents only a fraction of the cost of the completed tire, so the price of tires does not vary in the same proportion as the price of rubber. These same conditions, viz., that there are no substitutes for rubber, and that fluctuations in its price do not result in corresponding fluctuations in its consumption, explain why a slight underproduction is immediately followed by a sharp rise in prices and slight overproduction by a similar decline.

As already pointed out, changes in the prices of tires always lag slightly behind changes in the price of crude rubber, for one reason because the big tire manufacturers always contract for a supply of crude rubber at fixed prices in advance, and are, therefore, in position to maintain their old prices for a while after rubber prices have begun to advance. But it is generally understood that the tire prices established after the agreement last fall leave a rather narrow margin of profit, and revised schedules of tire prices may therefore be expected in the near future. It is not unlikely that the manufacturers of solid tires will take the initiative in this revision, as they did two years ago when rubber prices dropped, because the cost of crude rubber is a relatively more important item in solid than in pneumatic tires.

# Legislative and Legal Department of This Paper.

It is unnecessary to state that THE HORSELESS AGE is a technical journal, having for its purpose the dissemination of scientific and other useful information to all who are or may become interested in vehicles propelled by power on the public thoroughfares. The name Horseless Age implies a mechanical era in which there is to be a substitution for animal power, therefore much that is to be found in this publication has to do with mechanical engineering. With truth it may be said that THE HORSELESS AGE is the only American automobile periodical which is strictly a scientific journal. Fiction, stories of automobile picnics and the like are totally irrelevant to this paper. These can be found in other periodicals devoted to the publication of pictures and amusing rather than instructive and educating reading. THE Horseless Age is also something more than a purely technical journal of automobile mechanics. It seeks to cover the whole field of usefulness by briefly recording news of interest to thinking people and by acquainting its readers with important information concerning the use of the mechanically propelled vehicle on the public highways. Therefore, each week we devote considerable space to legislative and legal matter, which, though subordinate to the other subjects usually discussed, is of importance.

Just exactly how much space should be devoted to legal matters depends upon the importance of the subject to Horse-Less Age readers. We want to give the subscribers all they desire, and at the same time we do not want to overburden our readers with reading matter which may seem foreign and possibly dry or uninteresting.

That our legislative and legal department is justified and warranted has seemed beyond question. It is the law which allows the horseless carriage to exist and to be run; it is the law which regulates its locomotion; it is the law which protects and punishes its operator. In fact, very much that is said and done concerning the automobile seems to weave into it legal considerations, so The Horseless Age has, for this reason, sought to give to its readers the best thought on various legal questions involved that could be proceured.

The policy of this paper is and always will be to satisfy its readers; therefore, we would deem it a favor if our subscribers and readers would frankly advise us whether in their estimation too much or too little of any particular subject is to be found in our weekly issues. We want the paper as near perfect as possible, and any suggestions concerning the legislative and

legal or other departments will be greatly appreciated.

#### The Wheel Tax Idea.

A new phase of automobile legislation has recently developed in Maryland. In that State a new automobile law is at present under consideration, and in order that the subject might be handled intelligently the Governor of the State some time ago appointed an automobile commission to investigate the requirements as to auto legislation and to frame a suitable bill. This commission has been in conference with a committee of the A. C. of Maryland, and several points have been agreed upon between the two bodies which have been incorporated in a bill, while in regard to others there is disagreement. The Marvland motorists are willing to submit to a special tax on automobiles on the condition that a wheel tax be imposed on all wheeled vehicles, the receipts from which are to be used for highway improvement.

This standpoint is a new one for motorists to assume. In several of the States the motorists last winter offered to accept a special tax in exchange for concessions in the way of increased speed limits or the total abolition of such limits, but several of the bills drawn on these lines did not become law. The Marylanders are evidently more practical minded. Instead of approaching their Legislature with the proposition: "We are willing to be taxed if you will not interfere with our speeding," they made it: "We will pay for our use of the highways if other users are also required to pay." There can be no question as to the equity of this proposition. The only manner in which a special tax on automobiles can be held to be constitutional is by regarding it as a road tax-a tax for the use of the road. But if automobiles are taxed for using the public roads, it is no more than right that other vehicles should also be taxed therefor, because all sorts of wheeled vehicles have a destructive effect on roads, and conditions are even conceivable where a heavily laden horse drawn vehicle with narrow tires is more destructive to the road than a rubber tired automobile. The imposition of a wheel tax for the purpose of raising funds for road maintenance is a relatively new idea, as heretofore the public roads have been built and maintained with funds raised by general taxation. The wheel tax plan has been subjected to a rather severe as to its constitutionality in Chicago,

from which it emerged unscathed. The plan has one notable advantage, viz., that it permits of placing some restraint on the use of vehicles unusually destructive to the roads.

#### Accessibility of the Gear Box.

Accessible as are the motors of most modern cars it is unfortunately the case that the gear boxes of many cars of standard construction, some of them of the highest grade, are not easily gotten at. With the gear box as an independent unit, its location along the axis of length of the car is susceptible of some variation. The provision of adequate space for the universal joint between it and the clutch acts to determine its forward limit, and the rearward limit is fixed by the necessity of minimizing the obliquity of the propeller shaft.

The type of body which the chassis carries largely determines the accessibility of the gear case. If a touring body is used the gear box is too likely to be found directly under the front seat. As the gasoline tank is generally placed under this seat, the clearance between tank and gear case is likely to be very slight, with the result that it is very difficult to remove the cover of the box and even to reach the plug which permits of supplying lubricant to the gear set.

Inspection of the gears and even the replenishment of their lubricant is often neglected simply on account of the close quarters in which the work has to be done. In some designs in which this fault exists the gear box could seemingly have been placed somewhat further forward without unduly crowding the universal joint connecting the gear set with the clutch and without unfavorably affecting the weight distribution. Or, it could apparently be located a little further to the rear, so as to make it accessible by raising the tonneau floor boards, while not seriously increasing the angle of the drive shaft.

When a runabout or roadster body is applied to such a chassis the front seat is enough further to the rear so that the gear box, or at least the greater part of it, comes under the front floor boards, by the raising of which access to it may be had. If it has to be dismounted it may be necessary to remove the body for the purpose, especially if the gasoline tank is located elsewhere than under the seat, as is sometimes the case in runabouts.

In the unit power plant construction the

gear box, being affixed directly to the engine base, is well forward and accessible by raising the front floor boards. In the case of the rear axle mounted gear box, its accessibility is perhaps not quite so good as that of the unit power plant, but there is plenty of clearance above it and there is really no difficulty in getting at it.

It is well worth the while if designers in laying out chasses with independent gear boxes provide for their location so that they may be clear of the front seats of the vehicles to which they are to appertain. An inaccessible gear box means, in practice, a neglected gear box, and the latter too often means dissatisfaction upon the part of a customer.

# General Motors and Licensed Association.

The acquisition of the control of the Cadillac Company by the General Motors Company is of more interest than any of the other big deals of the latter which have preceded it, not only because the Cadillac Company is the largest concern yet acquired by the "trust," but also because it is the first firm within the "Licensed" Association to join the General Motors Company. Of course, the Buick Motor Company, the nucleus of the "trust," still has a Selden license, we believe, but it is not a member in good standing, having long since ceased to pay its license fees. The Cadillac Company has all along been one of the staunchest supporters of the Licensed Association. The statement was given out that the policies and management of the Cadillac Company would remain unchanged, but in view of the previous attitude of the head of the General Motors Company toward the Licensed Association. it is at least an interesting question what the Cadillac Company's attitude toward the Licensed Association will be under the new régime.

#### Vienna Motor Cab Failure.

The Vienna Motor Cab Company, Ltd., which was organized about a year ago by a French automobile house, with 92,000 crowns capital stock, with the object of introducing motor cabs in Vienna, has wound up business. The firm opened negotiations with several Vienna cab companies for the purchase of licenses. As a matter of fact it acquired only a single license, and it would seem from the failure of the enterprise that the substitution of the motor for the horse in Vienna involves great difficulties.

# Maintenance and Repairs

#### What Experience Teaches.

By "OWNER."

It is probably just as well that owners and chauffeurs of new cars do not know too much about them, because, as a rule, all a new car needs for the first season is plenty of oil in the right places in addition to its gasoline and ignition supples. But the second and subsequent years of a car's life are the critical times when experience is absolutely necessary to keep the car from deteriorating in value and usefulness. Nevertheless, despite years of experience, things will happen and a driver will ignore them until sometimes considerable damage is done.

The writer was driving his car one day when he heard a sharp crack, and was about to stop. One of the passengers said we had passed over a piece of wood which had broken with a snap; looking back we saw the piece of wood in the road, so we went on, assured that nothing was wrong. In a few miles another sharp crack was heard, and the passenger said we had passed over another piece of wood, but we stopped the car and got out and walked around and peered here and there, but found nothing wrong, and on walking back a short distance picked up a piece of the top of a soap box which had been split lengthwise in several pieces. It was reasonable to suppose that this had produced the noise when the car had passed over it, so we jumped in and went off again, free from care. The car ran splendidly for perhaps 30 miles, and we were but a few miles from home, going fast to get there in time for dinner, when again came the same sharp, distinct snap. The car was instantly stopped, because now we knew there was something wrong, and we could not be lulled again into a fancied security until that sharp snap was clearly and satisfactorily explained. It did not take long to find that three leaves of the right front spring were snapped clear through, and that nothing held the front axle from steering around, and perhaps ditching the car, but two small bottom leaves and the spring clips, which latter were loose and were fast working apart.

There might have been a dangerous accident because of our stupidity in not finding the cause of the first sharp snap, and we could have saved the price of a complete new spring if we had been cautious. It startled us somewhat when we found that nearly all the spring clips were so loose that you could turn some of the nuts with your fingers.

UNUSUAL NOISES WARNING SIGNALS.

Any unusual noice should cause the inver to stop instantly, and he should find

out the cause, if possible, and if no apparent cause can be found a thorough examination of the springs and the steering gear should be made before going on. Thereafter cautious driving should be the rule, until a complete examination can be given the car at home. Of course, no car should be driven a foot if there is a continued unusual loud noise, and even unusual clickings should be examined into, or great damage may result.

THE HORSELESS AGE.

Regardless of the continued expressions of supreme confidence that are heard from many drivers, the new owner should exercise at least as much care in driving a car as he would in driving a horse, and no man would dare to continue to drive a horse at speed if he considered for a moment that the carriage running gear was not in perfect order or that the harness was worn out; and yet the danger from weakness in a motor car is far greater than the danger existing in the case of a horse or carriage.

The person who continually warns his motor owning friends of the dangers attendant upon driving a car is somewhat of a bore. Nevertheless, the man who examines the vital parts of his car carefully before going out usually returns safe and sound, and surely the fact that such a driver feels confident in the knowledge that his car is solid and free from apparent defect in these vital parts cannot detract from the pleasure of a day's run.

#### STEERING GEAR MOST IMPORTANT.

Steering gear parts rank first in the catechism of safety; next come the brakes, then follow the springs. If these are strong there is comparatively no danger to life or limb. Defects in engine, transmission, body and accessories result in annoyance and delay, which are bad enough, but if taken philosophically and with patience, as they should be taken, they do not materially harm anything but the pocket.

The steering gear is of such vital importance that no car should be taken on the road for even the shortest distance unless all parts of the gear are in perfect order. Play in the steering wheel, of course, is not considered a great defect, as nearly all cars sooner or later develop this, but this is the only defect that should be tolerated.

The car may be driven at a slow pace even if the brakes are defective, provided no hills are to be encountered and the journey does not run through a crowded city. But no hill worthy of the name should be attempted, up or down, unless at least one set of brakes may be depended on. Of course, the engine can be used as a brake under certain circumstances and in experienced hands, but I have found that unless the low gear, or at least the second gear, is used, the engine is not much use on a steep hill. Going down a hill the use of the engine will check the speed, but you need the best of brakes in the best order to stop in an emergency.

CLUTCH AND BRAKE INTERCONNECTION.

In this regard it might be well to say that the coupling of the foot brake and clutch is not, in the writer's opinion, a desirable feature on a car, as it compels reliance to be placed solely on the engine as a check on the speed in descending hills or solely on the brakes. Experience has shown when taking a steep hill with the first speed engaged that the foot brake could be used to great advantage to help check the speed if it were disconnected from the clutch.

Where the clutch and brakes are connected and the engine is being used as a brake, it takes an appreciable space of time to take out the clutch and apply the brake, unless the emergency brake or foot brake is jammed on with great force. It will be found that on a steep grade the car will jump ahead with great speed while such a change is being made, a condition of affairs which is liable to shake the nerves of anyone but a reckless individual, and a driver needs his nerve when he is descending a long, steep hill with a loaded, heavy car.

On ascending a hill a separate foot brake disconnected from the clutch is invaluable in cases where gears are missed in changing down. This, of course, results, as a rule, in a stop, and an application of the brakes to hold the car until first speed is engaged. Unless the brake can be used alone it requires very delicate work to release the brake and apply the clutch. If you release the brake and do not apply the clutch quickly the car will start backward, which will involve the quick application of foot and emergency brakes. If, on the other hand, you release the brake and let in the clutch too quickly you are very likely to stall the engine.

The writer had an entertaining experience on a very steep, winding hill driving a car with clutch and brakes interconnected. Rushing the hill on the fourth speed we were forced quickly to third, second and then to first on the steepest part, about three-quarters of the way up, where the road made a sharp turn. The engine was gallantly pulling away, hoisting the car up the heavy, sandy road at about 4 miles an hour, when an ominous crack was heard under the footboard; the engine raced like a dynamo and the car gathered stern way down the winding, twisting hill. On went both brakes instantly and the car brought up solid.

#### BRAKE LEVER INSECURELY LOCKED.

As the catches on the brake lever were somewhat worn and the lever was liable to release itself when put on hard, the driver was afraid to leave his seat until the car was secure from backing down the hill. As the passengers were all women no aid could be expected from that quarter, so they were asked to alight and take a walk to view the scenery. No stone large enough to block the wheels being in view, the car was backed down slowly into

the ditch so that it was secure from any movement. Examination of the car showed everything in good order, so far as could be seen. The engine turned over, the clutch shaft ran freely with the gear in neutral and held firmly when in first speed. So, deciding to put the car to the only proper test, the engine was started and the first gear put in, and the car pulled out of the ditch in good shape. Taking the passengers aboard we retraced our way down the hill, and the car performed properly on all speeds. It was not until some weeks afterward that the cause of the ominous crack was discovered. On taking the same hill on first speed the change speed lever jumped out of the notch with the same sharp crack that we had previously heard and the car stopped as before. The journey up the hill was continued with the lever kept in place by the hand without further trouble.

It is unnecessary to say that both emergency brake lever and change speed lever were put right immediately on finding out these defects.

#### Scottish Reliability Trial Awards.

A complete report of the above trials appeared in our issues of June 30 and July 7. The awards have now been announced by the judges. Efficiency gold medals in each class have been awarded as follows:

ionową.	Marks.
Class A-10 h. p. Riley	989.9
Class B-12-18 h. p. Riley	976.9
Class C-10-12 h. p. Humber	995.9
Class D-14-16 h. p. Argyll	985.9
Class E-16 h. p. Humber	994.9
Class F-24 h. p. Vauxhall	995.1
Class G-30 h. p. Adler	976.6
The season and the secondary in an	-4

The total possible of marks in each case is 1,000.

In each of Classes D and E, in consid-

In Class H there was only one competitor who completed the trial, and the committee, on account of the number of marks lost for repair of detachable wheels, have not seen their way to award a medal in this class.

Bronze medals, awarded in each class to the car gaining the highest number of marks for hill climbing, have been awarded as follows:

as ronows.	viarks.
Class A-10 h. p. Riley	50
Class B-12-18 h. p. Riley	50
Class C-12 h. p. Star	
Class D-15 h. p. Star	49.1
Class E-16 h, p. Humber	47 - 7
Class F-24 h. p. Vauxhall	47 - 1
Class G-38 h. p. Minerva	50
Class H-50 h. p. Ariel (only competitor).	

Total marks possible 50.

The Scottish Cup for the vehicle showing the lowest fuel consumption per ton-mile over the whole trial has been gained by the 38 horse power Minerva, with a consumption of .02244 gallon per ton-mile, equal to 44.57 ton-miles per gallon of fuel.

# Injector Carburetors for Heavy Fuel.

(Paper read by F. Duerr before the Automobile Technical Association at Frankfort-on-Main.)

The lighter grades of gasoline, of 0.680-0.700 specific gravity, have ceased to be regarded as the only fuels for automobile motors. The frequent variations in price of this fuel and the sometimes exceptionally high price have been the causes which led to a search for other, cheaper fuels. A considerable number of manufacturers have endeavored to perfect suitable apparatuses which would

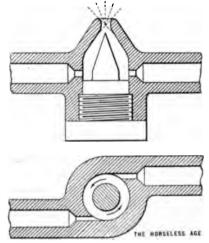

Fig 1.

make it possible to use these cheaper but heavier fuels.

Of these fuels benzol deserves to be mentioned in first place, and its use is constantly increasing. There are some exceptionally volatile grades of benzol which may be vaporized as readily as the lighter grades of gasoline. That a large proportion of the carburetors so far used are not immediately applicable to the use of benzol is due to the chemical properties of this fuel. Benzol contains a much greater proportion of carbon and a much smaller proportion of hydrogen than gasoline. The processes of combustion of these two elements are different. On combustion both form carbonic acid and water. But as one atom of carbon requires two atoms of oxygen for its combustion into carbonic acid (CO2) and one atom of hydrogen only one-half atom of oxygen to form water (H2O), it follows that hydrogen requires only one-fourth as much oxygen for its combustion as does carbon. Consequently, if a fuel contains much hydrogen it requires little oxygen, and if it contains much carbon it requires much oxygen for its combustion. In practice the oxygen required for combustion can be supplied to the cylinder only in the form of atmospheric air, and it follows from this that a benzol carburetor must have a much greater amount of air supplied to it than a gasoline carburetor. Most of the older carburetors would not operate on benzol because, although the air received by them was sufficient for operation on gasoline, it was insufficient for operation on benzol.

From the time that benzol began to compete with gasoline, the problem presented itself of designing a carburetor which would work equally well with either fuel, and this problem may now be regarded as solved.

The fact that benzol is constantly being more extensively used, owing to its low price, has led a number of gasoline distillers to determine whether it is not possible to use a heavier grade of gasoline than that commonly employed, which varies between the limits of 0.680 and 0.720 specific gravity. It was, of course, to be foreseen that satisfactory results could be obtained if the carburetor were pre-heated or the motor started with a lighter grade of gasoline. The question, however, came up whether it was not possible to start the motor cold with such heavier gasoline. It may here be remarked that whenever the term "heavy gasoline" is used in this article a distillate of more than 0.750 specific gravity is referred to. The heavier grades of gasoline vary with respect to volatility according to their origin, some of them being quite readily vaporized, and others, again, being entirely impossible to vaporize without the application of heat. The purchaser who knows only the specific gravity of the fuel has no means of telling whether the fuel may be vaporized easily or only with difficulty. Only carburetors should therefore be used which will handle the least volatile fuel without trouble.

After vaporization had been disposed of there was only one possible solution of the problem, and that consists in dividing the fuel mechanically into very fine particles so that it is, in a sense, separated into its molecules, and every one of the molecules is surrounded by sufficient air so that complete combustion is possible. Now, we possess a whole

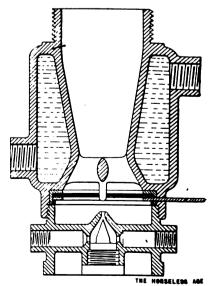

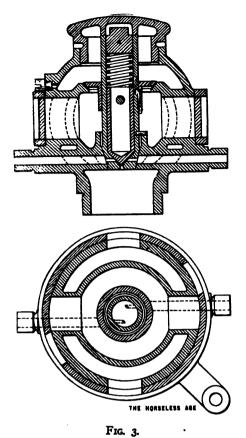

FIG. 2.

series of apparatuses for finely spraying fluids. Practice, however, has shown that these spraying devices do not divide the gasoline into sufficiently fine particles, and a pointer as to how this exceedingly fine division of the fuel may be most rationally effected has been obtained from the Diesel motor. The purpose is accomplished by making use of air for spraying the fuel. Another requirement is that the spraying may be effected without special resistances. It is obvious that the fuel will be sprayed the finer the greater the difference in pressure between the space into which the sprayed fuel enters and the space from which the fuel and air arrive. That is to say, if we provide an arrangement which makes it possible to supply the fuel and the spraying air to the spraying nozzle under pressure, we will secure a very fine division, the fuel particles will be smaller, and will therefore be easier to surround each particle with a sufficient amount of air to effect its complete combustion; the thermal efficiency will be increased and the operating cost decreased.

The simplest method of effecting this spraying of the fuel consists in imparting a rotary motion to a fine jet of fuel and a fine jet of air, and after they have attained a certain velocity, forcing them to escape through a common spray opening. The accompanying sketch shows such a spraying arrangement. The horizontal cross section, Fig. 1, shows two channels opening tangentially into a conical space. As already pointed out,

the fuel enters from one side and the air from the other. During the suction stroke of the motor a partial vacuum is created in the conical space c, Fig. 1, the fuel and air enter with considerable velocity into this space and move helically along the periphery of the conical space, toward the spray opening d, as is indicated in the vertical section. The lighter air escapes at a higher velocity, overtaking the fuel, thereby constantly detaching small particles of the latter. At the spray nozzle opening the escaping mixture of air and fuel forms a coneshaped body of mist, which greatly facilitates the mixing of the two elements.

The application of this spray nozzle in a carburetor is illustrated in Fig. 2. The spray nozzle is located in the lower part of the carburetor, and directly above it there is an iris shaped valve designed to permit of regulating the opening, which is capable of rotating around a stem If the iris is fully opened the fuel, mixed with additional atmospheric air, will flow through the carburetor, whose mixing chamber can be suitably heated by means of exhaust gases or circulating water.

It is, of course, also possible to develop the injector nozzle so as to operate mechanically, and the writer considers the mechanical injection the most appropriate method of fuel supply, which, moreover, has long since been adopted on stationary motors. Another design of carburetor in which the admission of fuel is controlled automatically by the suction of the piston is shown in Fig. 3.

## Southern California Club's New Ouarters.

The A. C. of Southern California has rented the ground floor of the building at 323 S. Hill street, Los Angeles, where headquarters will be established. During the first five months of the year the club's membership was doubled. Ito new names being added to the membership rolls during June. The club is carrying on an active campaign for the erection of signboards throughout the southern part of California and has obtained appropriations equal to its own contributions from several boards of county supervisors. The club is establishing branches in all the counties of its jurisdiction, consuls taking charge of the local work in conjunction with the directors of the general organization.

# Monarch Motor Car Company Bankrupt.

The Monarch Motor Car Company, of Chicago Heights, Ill., was thrown into involuntary bankruptcy on July 9, with liabilities estimated at \$50,000 and assets of half that amount. David Davis, of New York, was one of the pétitioning creditors. Preferential payments are alleged to have been made. The American Trust and Savings Bank was appointed receiver.

# The Historical Development of the / Truffault-Hartford Shock Absorber.

A circular recently issued by the Hartford Shock Absorber Company gives an interesting historical résumé of the introduction of shock absorbers in this country by Edward V. Hartford, and the development of the device up to the present time. The circular is herewith condensed.

In the fall of 1897 Mr. Hartford went to live in Paris, and in the fall of the following year he was delegated by the Marquis De Dion, one of the founders of the French automobile industry, to try to establish a branch of the De Dion-Bouton automobile business in the United States, raising the necessary capital here. Mr. Hartford states that his mission failed entirely, as American investors at that time were not willing to venture any money in automobile enterprises.

In the spring of 1899 Mr. Hartford attended a 100 kilometre motor tricycle race at Versailles. More interest was being taken in tricycles in France at that time than in automobiles, for the reason that the former were faster. The race was won by Marcellin on a Darracq tricycle equipped with a 12 horse power, two cylinder Buchet motor, who defeated Baras, who up to that time had been regarded as the champion tricycle racer of France. Both Marcellin and Baras rode tricycles of the same make and horse power, but Marcellin's machine was fitted with a special front fork, known as the Truffault fork, and his victory was ascribed by himself and by Baras to the use of this device.

Mr. Hartford was much impressed with what he had seen, and the next day looked up M. Truffault, whom he found working in a little shop near the Porte Maillot, in Paris, assisted by his two sons. Truffault was a man about sixty years of age and a typical inventor. Mr. Hartford had the Truffault fork applied to his own 21/4 horse power De Dion tricycle with very gratifying results. He and Truffault became friends and worked together on the shock absorber problem, adapting these devices to automobiles. The present three point suspension is claimed by Mr. Hartford as one of his ideas. Mr. Hartford came back to America in the fall of 1900, and sent a 6 horse power Oldsmobile over to Truffault to experiment with. This was the first car ever fitted with a complete set of shock absorbers, all previous experiments having been made with tricycles. The idea of applying a friction brake to the springs was ridiculed by many automobile engineers at the time. and it was even suggested that instead of retarding the action of the springs by friction they should be fitted with ball bearings so they would act as freely

Mr. Hartford shortly after his return to America met a representative of a large automobile manufacturer and began negotiations with him regarding the manufacture of the shock absorbers in this country. In order to help matters along he had M. Truffault come over from France and stay at the factory of the manufacturer referred to for two weeks. fitting the car turned out there with lighter springs all around and applying shock absorbers. When the car had been equipped it was subjected to a most searching test, at the conclusion of which the manufacturer made an offer of \$1,000 for the Truffault patent. As this was little more than had been expended in making the demonstration, including the trip of Trauffault from France and back, the offer was declined.

Truffault upon his return to France entered into a contract with the Peugeot firm, by which the latter was to have the exclusive use of his patent in France. Peugeot at once fitted all his own cars with shock absorbers, and also supplied a few sets to other manufacturers. It was after the victory of Thery on a Richard-Brasier racer in the Gordon Bennett race in June, 1904. that shock absorbers became extremely popular. There drove one of the lowest powered cars in the race, and his success was ascribed largely to the fact that owing to the use of shock absorbers his wheels kept the road, and thus the power was economized, and the tires and the whole mechanism of the car were saved. From that time on shock absorbers have been invariably fitted to all racing cars, and also to a majority of big touring cars.

In this country the shock absorber business was started by Mr. Hartford in 1903. An initial order for twenty-five sets was placed with the Garvin Machine Company, of New York, and after this had been duplicated twice a small shop was opened on Hudson street in October, 1903. In May of the following year the demand had become so great that it was necessary to work day and night. Mr. Hartford states that they are now manufacturing 50,000 shock absorbers a year, and he claims that they have always done at least 90 per cent. of the shock absorber business in this country. The success of the device was well illustrated by the numerous imitations which flooded the market at one time, many of which disappeared again soon, however. Mr. Hartford states that they have endeavored to turn out an article of the best materials which should give no trouble to users, and asserts that their shock absorber is the only one adopted by car manufacturers as regular equipment.

The Royal A. C. of Great Britain and Ireland is planning to hold a trial of tire protectors over a distance of 4,000 miles, 3,000 of which is to be on roads and 1,000 on the cemented Brooklands track.

Good Roads Convention Dates Set.

At a meeting held in Cleveland last week

At a meeting held in Cleveland last week the dates for the second annual good roads convention to be held in Cleveland were set for September 21-23. The United States Government has named as its official representative Logan Waller Page, direcor of the United States Office of Public Roads. Co-operating also with the A. A. A. will be the National Grange, the American Road Makers' Association and all of the automobile organizations representing the various manufacturing interests.

Governor Harmon of Ohio has consented to represent his State at this convention, and he will speak on the "Good Roads in Ohio." Mayor Tom L. Johnson of Cleveland will deliver the address of welcome. Congressman R. P. Hobson of Alabama will deliver an address on "National Aid and Post Roads." Among the other speakers selected for the tentative program, with their subjects, are:

"The National Grange and Good Roads," N. J. Bachelder, master of the National Grange.

"State Aid," James H. McDonald, State Highway Commissioner of Connecticut.

"Economics of Road Building," Samuel E. Hill, president National Good Roads Association.

"Road Situation in the United States as Compared with Foreign Countries," Logan Waller Page, director United States Office of Public Roads.

"Macadam Roads," A. B. Fletcher, secretary Massachusetts Highway Commission, or some other speaker to be selected by the Massachusetts Highway Commission.

"Bituminous Road Materials," Provost Hubbard, chemist of the United States Office of Public Roads.

The closing day of the convention will be devoted to a series of tests on macadam roads, to study methods of abating the dust nuisance, and there will also be practical demonstrations with different materials of road building conducted by Director Logan Waller Page. The Cleveland A. C. will take the delegates on a tour of inspection over the improved roads in the vicinity of Cleveland.

#### Los Angeles on Speeders' Trail.

As a result of two fatal and half a dozen other accidents resulting in permanent injuries to pedestrians within the last three months, the city officials and the press of Los Angeles are co-operating in an effort to stop the speed fiends by drastic measures. Three menths ago a labor union leader was struck and instantly killed by a joy rider. On Saturday, July 3, I. Lowman, a well-to-do merchant, was shockingly maimed and instantly killed when he endeavored to cross the street in front of two automobiles engaged in an impromptu race, stepping directly in front of a third machine he had been unable to see. M. C. Abrams. the driver of the machine, employed by a firm of accessory dealers, was arrested

and charged with manslaughter. Twentyfour hours after the tragedy another automobile at racing speed struck a pedestrian, threw him twenty feet and left him unconscious on the curb. The driver did not stop but was arrested after a race of five miles with police officers who impressed a passing motor car. A week before these occurrences a driver, found guilty of having run over a pedestrian and continuing on his way laughing loudly, was fined \$300 and sent to the workhouse for thirty days. His victim appeared in court on crutches, having lost the right leg above the knee as a result of the accident. Hundreds of complaints have been received by the authorities concerning the recklessness of joy riders and public sentiment is deeply aroused

Mayor Alexander, in a message to the city council, recommended the passage of an ordinance reducing the speed limit outside the business district from 20 to 15 miles an hour, raising the minimum fine for the first violation to \$25, for the second offense to \$100 and for the third infraction he favored the imposition of a straight jail sentence of not less than thirty days. Several councilmen declared themselves in favor of reducing the speed limit throughout the city still further, but, as a result of the efforts of the A. C. of Southern California and the newly organized Motorists' Protective Association, calmer counsel prevailed. A committee comprising several councilmen and representatives of the motorists' associations, together with the chief of police, was appointed to frame a new ordinance for submission to the council, and in all probability this ordinance, while not disturbing the present speed limits, will provide for the licensing of drivers and contain a provision for a compulsory jail sentence for reckless offenders. That a jail sentence clause is needed, both for the protection of the public and of the vast majority of law abiding autoists, is shown by the steadily increasing number of accidents-104 in the first five months of 1008. 142 for the same period of 1909-and by the enormous number of fines imposed as a result of the work of but two motorcycle officers mounted on slow machines. The automobile men offered to provide 200 representative citizens and motor car owners, to serve as special officers in running down reckless drivers.

#### Tendered Bad Check for Car.

Joseph W. Smith, twenty years old, was arrested at Indianapolis a few days ago after he had tendered a check for \$2,800 to an automobile concern for a touring car. He represented that he had been left considerable money and he made a good impression on the company. He purchased the car after the banks had closed at noon on Saturday, saying he would call the following day for the car. However, the company found the check was bad and Smith was arrested when he called for the car.

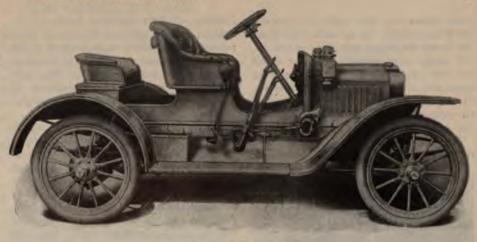

### **NEW VEHICLES AND PARTS**

#### New Maxwell Small, Four Cylinder Car, Model O.

Right in line with the latest development in the automobile industry the Maxwell-Briscoe Motor Company, of Tarrytown, N. Y., last week announced a new four cylinder, 22 horse power runabout, selling at \$850. The same car is furnished with a single rumble seat for \$875 and with a double rumble seat for \$900. Two characteristic features of the car are a three speed sliding pinion change gear and a high tension magneto with dry battery auxiliary. The unit power plant construction characteristic of all Maxwell cars is also found in this new model. Deliveries of the new model, which is made at the Providence plant, will begin this month.

The motor is of the four cylinder, vertical type, of 334 inch cylinder bore by 4 inch piston stroke. The cylinders are cast in pairs. The motor is claimed to develop 22 actual horse power at the normal speed of 900 r. p. m. The water jackets are cast integral with the cylinders, and the valves, located on opposite sides, are interchangeable and exceptionally large. Both inlet and exhaust valves are mechanically operated. The tappet rods are hardened and ground, and their guides are of phosphor bronze. The cams are hardened and ground and enclosed within the crank case, and are lubricated by splash. Three large bearings are provided for the cam shaft, the shaft itself being hardened and ground. The crank shaft is a drop forging, finished by grinding. The connecting rods are steel drop forgings with bearings of compressed babbitt. The connecting rods may be reached through hand holes on each side of the crank case provided with cover plates which are quickly removable. The motor is very similar to the Maxwell Model D. A. 30 horse power.

The sliding pinion change gear gives three speeds forward and one reverse, direct drive being on third speed. Roller bearings are used throughout. The gears

MAXWELL MODEL O.

are drop forged, carefully cut and hardened. A feature of this transmission is the positive gear lock which prevents the shifting of gears when the clutch is engaged.

The Maxwell-Briscoe Company makes the claim that the first multiple disc clutch for use on an automobile, either in this

MULTIPLE DISC CLUTCH.

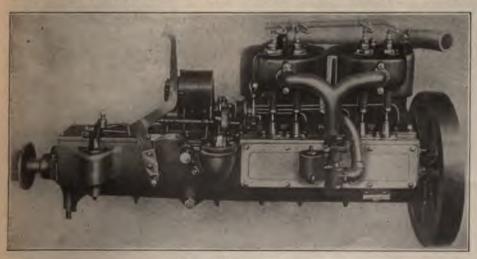

country or abroad, was used on the first experimental Maxwell model built at the end of 1903. The new model is fitted with an all-metal multiple disc clutch, consisting of fifteen saw steel discs, each disc being concave about 1-32d of an inch, a construction which causes the clutch to engage gradually. The steel discs run continually in a bath of oil, which practically eliminates wear and permits of the slipping of the clutch without injury to the plates. The thrust from the clutch spring is taken up by a large ball thrust bearing.

The carburetor is of the constant level float-feed type and is of the company's own design. A needle valve adjustment regulates the amount of gasoline, and a simple adjustment at the top of the carburetor the amount of air. The thermosiphon cooling system has been retained in practically the same form as used on the 30 horse power, four cylinder model.

The oil is carried in a tank located under the hood, from where it is forced through a single sight feed located on the dash, whence it is distributed to each cylinder and to the clutch department. A glass gauge on the oil tank shows through at the dash, so that the operator can at all times see the amount of oil contained in his tank. A positive oiling device supplies oil to each cylinder. This consists of an oil ring fitted at the bottom of each cylinder. This ring is constantly supplied with oil by the mechanical oiler and into it the lower end of the piston dips at each stroke, carrying with it enough oil to copiously lubricate the cylinder. This device is claimed to prevent the flooding of the cylinders with oil and to eliminate the tendency to carbonize.

The drive is by a propeller shaft fitted with two self oiling universal joints. The rear axle is of the bevel gear type and the gears are drop forgings, carefully cut and hardened. Both the main drive gear and the pinion are exceptionally large. The shaft of the driving pinion is carried in two roller bearings. These bearings are lubricated by a large self feeding grease cup. The second feature in connection with this rear axle is a special thrust roller, hardened and ground, and fitted against the main bevel gear. This device holds the main drive gear firmly against the pinion.

Two sets of brakes, of the internal expanding and external contracting type respectively, are mounted on the rear hubs. The internal brake shoes are of cast iron, expanding against a steel drum. The ex-

Model Q Power Unit.

ternal shoes are lined with an asbestos lining and contract on the same steel drum. The brake dimensions are 1½x9 inches.

A single lever controls both the clutch and the external brake. The emergency brake also automatically releases the clutch. The spark and throttle levers are located on opposite sides and immediately under the steering wheel.

The frame is of pressed steel and hotriveted throughout. The front springs are

SELF LUBRICATING UNIVERSAL JOINT.

32x134 inches, and the rear springs 36x134 inches. Strut rods are placed between the rear axle and the frame so as to take the driving effort off the rear springs. The wheels are of the artillery pattern and of selected second growth hickory. The tires are 30x3½ inches, of the standard clincher type. The wheel base is 93 inches and the tread 56 inches.

Thorough protection to the engine and transmission from mud and dust is afforded by a pan extending from the radiator to the rear end of the gear box. Metal extensions are also provided from the frame to the running board and from the frame to the fenders, so that the car can be driven through deep mud without splashing the body, or the passengers. The body is made of sheet steel with moldings. The upholstery is of leather and curled hair. All cars will come ironed for top.

#### Almond Flexible Metallic Tubing.

Flexible, all metal tubing, composed of specially wound spirals of steel wire, is now upon the market and is coming into quite extensive use for automobile purposes. Although no rubber or other nonmetallic packing is used in its manufacture it is claimed to be perfectly liquid and gas tight. It will not kink, but is very flexible. and it is claimed that repeated bending does not cause it to leak. The one-half inch size will bend into a circle of 8 inches diameter without damage, and the smaller sizes will withstand proportionately greater flexures, the curves in which it arranges itself, when in use, being very easy and gradual.

Wherever it is desired to convey oil, grease or gas this tubing may be used, and all elbows or other fittings, save the end connections, may be done away with, no matter how irregular the path taken by the tube may be. The labor of making the usual pipe connections and the

liability of their working loose by vibration may be obviated by its use. This tubing is not furnished in lengths to be cut up by the user, but can be obtained in any specified length up to 10 feet, with the fittings on each end as specified. It is not recommended for water connections.

Wherever oil leads of copper tubing are found to be liable to breakage from vibration this tubing should be applicable with advantage, and its somewhat high cost warranted. It is being used to quite an extent for oil or grease leads to inaccessible parts of the car mechanism, the ends of which may be brought out to handy positions upon the side frame members or elsewhere for the ready attachment of an oil or grease gun.

The hot air collecting device for the carburetor is frequently located upon the opposite side of the motor from the carburetor itself, and somewhat devious piping is required to effect the connection. For this purpose this tubing has been somewhat used, eliminating all angles in the connection, and thus reducing gaseous friction. On motorcycles, where vibration is very intense and pipe fittings frequently work loose, this tubing is recommended for intake and exhaust connections. Indeed, flexible tubing of this kind has been used for the exhaust connections of some automobile motors. Its employment obviates all abrupt turns in the path of the exhaust gases and tends to reduce back pressure as well as the noise which arises from abrupt changes in direction of the exhaust flow. The internal surface of this tubing is naturally not quite so smooth as that of regular pipe, which quality may somewhat counteract the good results of the easy curves in which the pipe arranges itself.

Tubing of this kind is manufactured by the T. R. Almond Manufacturing Company, Ashburnham, Mass., in various sizes.

#### Novel Stocking Cutter.

The accompanying cut shows a new stocking cutter recently designed by the Brown & Sharpe Manufacturing Company, of Providence, R. I. This cutter shows a departure from the general design of stocking cutters in that it embodies in its construction a new principle. Each alternate tooth is stepped. The particular cutter shown is 13 inches in diameter and of 1 inch diametral pitch, which is an unusually large gear cutter. A cutter of this design cuts easier and at faster feeds and speeds than the ordinary stocking cutter, because every other tooth is stepped, tending to break up the chips, which relieves to a large degree the stress on the cutter. It is also a distinct improvement over step stocking cutters which have all teeth stepped, in that they take a cut the shape of the cutter itself, while this cutter cuts more nearly to the exact shape of the tooth space, leaving little stock for removal by the finishing cutter, just enough in fact to insure the accuracy of the gear teeth.

The design of this cutter is exceptionally strong, and the cutter is able to easily take heavy cuts without undue strain on the teeth or driving clutches.

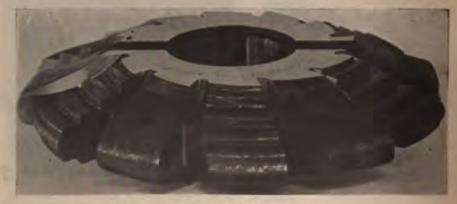

#### Lane Steamers for 1910.

The Lane Motor Vehicle Company, of Poughkeepsie, N. Y., will offer four models the coming season, including a runabout, a five passenger touring car, a seven passenger touring car and a close coupled vehicle. These are built on two chasses of 20 and 30 horse power respectively. The 20 horse power is fitted in runabout and five passenger bodies, and the 30 horse power with close coupled and seven passenger bodies The general design of these cars remains the same as last year, but a substantial reduction has been made in the prices. The runabout will be known as Model 19 and will sell for \$1,250. The five passenger car will be known as Model 20 and will sell for \$1,500. The close coupled car will be known as Model 21 and will sell for \$2,400. The seven passenger car will be known as Model 22 and will sell for \$2,500. All cars will have aluminum bodies and fenders,

#### Cartridge Coil Company's New Switch.

The Cartridge Coil Compary, of Lafayette, Ind., have recently put a new switch on the market which is well made and embodies a feature designed to appeal to the makers and users of cars equipped with two ignition batteries.

The switch enables the operator of the

NOVEL FORM OF B. & S. GEAR CUTTER.

"Switch WITH A MEMORY."

tell which battery was furnishing to the last time the motor was run, or this reason the manufacturers call the switch with a memory." The also reverses the direction of curhrough the coil, thereby preventing cation of the core of the coil, and also ng the pitting of the vibrating points, invariably occurs when the current is flows in the same direction.

switch is enclosed in a circular brass with either satin finish or enameled. The removable key furnished for ing the switch has a hard rubber and is so designed that it cannot be duplicated. The construction of the prevents a nail or piece of wire used in lieu of the key, so that when

#### Ioltzer-Cabot Portable Electric Drill.

y is removed the switch is locked.

Holtzer-Cabot Electric Company, of line, Mass., are marketing two types etric bench drills, one of which is

HOLTZER-CABOT DRILL

th illustrated. This drill is designas Type U. D., when wound for diarrent, and Type U. A., when wound ternating current. The motor is of with horse power, and is contained in reular iron base. An extension of mature shaft projects through the sost, which is located on top of the and drives the spindle by means of a belt, which is tightened by an idler the width of the two speed grooves shown. The current consumption running free is one-half an ampere; driving a drill it is dependent upon

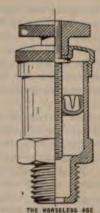

the size of the drill and the nature of the material being drilled. The chuck takes drills up to fifteen-sixty-fourths of an inch in diameter, and the maximum distance from the table to the chuck jaws is 43% inches. The height over all is 21½ inches, the maximum width is 9 inches, the depth 11 inches, and the distance from the drill spindle to the point where the table joins its support on the post is 31% inches.

The direct current machine is made with two speed variations, 800 to 1,600 or 1,200 to 2,700, and the alternating current machine, wound for sixty or 133 cycles, has the same speeds, but the machine wound for forty cycles is made only with a speed of 800 and 1,600 r. p. m. The net weight of each of these machines is 50 pounds, and they are wound for either 110 or 220 volts.

The other drilling outfit manufactured by this company is designated as No. 5, and is designed to operate only at 110 or 220 volts on direct current circuits. The motor is clamped to an upright spindle secured at one edge of the circular base plate, and may be adjusted vertically. The table is also adjustably clamped to the upright post and the chuck, which is mounted directly on the armature shaft, will take drills up to one-quarter inch in diameter. The speed of the drill ranges between 1,800 and 2,000 r. p. m., and the weight of the machine is 50 pounds. All of the above machines may be operated from an ordinary incandescent lamp socket.

#### Bennett Handy Grease Cup.

The Bay State Stamping Company, of Worcester, Mass., have recently brought out a grease cup which, with the exception of the thumbscrew, is made entirely of sheet metal. As shown by the illustration, the threaded shank permits the cup to be fitted flush with the outside of the bearing, so that only the body of the cup projects. The knurled head screw which actuates the sheet metal piston to force the grease from the cup is rotatably secured in the cap

BENNETT HANDY GREASE CUP.

which is threaded on the body of the cup. At no time does the screw project from the cap farther than shown, the piston being forced down by the action of the screw, because a lip which engages a groove in the cup prevents the piston from turning. The makers state that the piston fits the body of the cup air tight, and that if the grease became hot and melted it would not run out, because of this good fit.

#### The Dobbs Radial Light.

Arthur E. Dobbs, of 116 West Fourth street, Winona, Minn., has invented a mounting for headlights, by which the lights are automatically turned in the direction the car heads. Mr. Dobbs informs us that the methods of mounting the lamps on different makes of cars are covered by patents. As may be seen from the accompanying cut, the mechanism is quite simple, and is not at all conspicuous on a car. It consists of four levers (weighing less than two pounds), connecting the two headlights, which remain in the same location on the car, with the steering crank. It enables the driver of the car, without inconvenience to himself, and without forethought, to throw the light on the ground over which the car is to pass, by simply steering his car. It enables him to see

DOBES RADIAL LIGHTS.

where he is going, at the sharpest turns, as well on long curves on the road.

Being connected to the steering crank and not to the wheels, the up and down motion of the car on the springs does not affect the lights, nor is any lost motion, which may be in the front wheels, imparted to the lights.

The construction is claimed to be such that it will outwear any steering gear and could not be damaged without serious injury first occurring to the radiator or the steering gear. When properly adjusted to a car it is said to require no further attention.

By simply removing a pin from the steering crank, the lever connected to the lamps can be slipped off of the steering crank and on to a stationary pin, thus making the lamps stationary when not lit.

#### Chauffeurs Need Special Authority for Pledging Employers' Credit.

Judge Emden, in Lambeth County Court, England, a short time ago decided that a chauffeur is not entitled to pledge his emplover's credit without special authority to do so. An automobile repair man brought suit against a private owner for a sum of £25 10s. 7d. for repairs which he had made to the owner's car. An item of £3 5s. car hire was admitted by the owner, but as to the rest the defendant stated that the repairs had been ordered by the chauffeur without his knowledge or consent. The plaintiff gave evidence that the repairs were ordered by the chauffeur, and pleaded that the charges were reasonable, and that he paid no commission to the chauffeur. The judge, in giving his decision, stated that the question to be decided was whether the chauffeur had any implied authority to pledge his employer's credit. He said that although in case of emergency it might be possible that the same laws as in the case of ships applied there certainly was no expressed authority, and he held that there was no implied authority, as there was no emergency, to pledge the employer's credit. The judge pointed out that the case was of the greatest importance to automobile repairers, who, before starting on a job, should procure the authority of the owner of the car. The chauffeur stated that the accepting of commissions by chauffeurs was of everyday occurrence, but it was a highly salutary thing that the new law should be brought to bear in such matters strongly against any persons guilty of entering into such a contract. It was held that the plaintiff was not entitled to recover, except on the item admitted by the defendant

#### Boston's New Park Rules.

The Metropolitan Park Commission, of Boston, has increased the speed limit for motor vehicles on the roads and parkways under its control to 20 miles per hour, beginning August 1 next. Formerly the speed finit was 15 miles per hour, and only 10 files per hour in certain sections. Under

the former rules automobiles were excluded from that portion of Revere Beach reservation lying between Revere street and Revere Beach Parkway between 2 o'clock p. m. and 11 o'clock p. m. on June 17, and during the same hours on Saturdays, Sundays and legal holidays, between June 16 and September 14. Under the new rule automobiles are now excluded between 3 and 10 o'clock p. m. on the days mentioned.

# Publisher Munsey to Test Auto Reliability.

Frank A. Munsey, the newspaper publisher, is organizing what he calls the Frank A. Munsey Reliability Contest, and for which he has obtained an A. A. A. sanction. The course will be from Washington, D. C., to Boston and back over a different route, and the date selected is September 22 to 29, inclusive. One of Mr. Munsey's newspapers says that the tour gives promise of being of immeasurable benefit to the automobile trade.

#### Contact Area and Road Wear.

H. R. Mallock, F. R. S., recently read a paper on the new conditions of road construction since the coming of motor vehicles before the Institution of Civil Engineers in London.

He has made experiments on the area of contact between various paving materials and tires. The softness of rubber tires gives a larger area of contact and greatly reduces the mean pressure. The contact area of each tire on a London motor omnibus was approximately 13 square inches, giving a mean pressure of 120 to 140 pounds to the square inch. For an iron tired wheel of the same radius the area of contact would be 0.6 square inch and the mean pressure 3.000 pounds to a square inch.

With pneumatic tires it was nearly correct to take the pressure on the ground as uniform over the whole area of contact and equal to the air pressure in the inner tube. The area of contact was obtained by dividing the load by the internal pressure.

With regard to the effect of speed, the destructive effect could not be less than proportionate to the square of the speed, with a constant deducted, and it might be greater when the speed was high enough to make contact discontinuous. The distribution of pressure was changed with the stages of compression and expansion in the road over the area of contact.

#### New Road Material.

A practicable and inexpensive substance—the Everitt-Metropre-Fland material for the construction for the characteristic plane upon the market Wisconsin had an home fells work that the first income for which the many committees of "tailings," the results of the rounds had in order of mills for grinding tree, howelves their constructions which the same as a substitute for crushed at me for miles to be limited to the material now commonly used.

The discovery has interested Governor John in home and tool chest.

A. Johnson, of Minnesota, who visited the Wisconsin fields recently and investigated. At one mine alone there are 80,000 tons of tailings, which are given free for the hauling, and business men of the cities in the mining districts have adopted Governor Johnson's suggestions and are already spreading them over the roads, then packing them by means of steam rollers. The tailings include limestone, which obviates the need of any sort of binder for the top dressing.

# Bartholomew Company Buys New Factory.

J. B. Bartholomew has purchased the old Sieberling factory in Peoria Heights, Ill., for \$14,000. The plant was built by the Sieberling Company some twenty years ago, and used for the manufacture of bicycles during the height of that industry. In recent years it was occupied for a short period by the St. Louis Automobile Company, which failed some time ago. It is the intention of the new owners to manuture the heaviest parts of Glide cars, such as axles, steering gears, etc., in the newly acquired plant. The company is urging the town to construct an improved road leading to the factory.

#### New Jersey Ocean Boulevard.

A meeting of the New Jersey State Highway Commission with freeholders of Cape May, Ocean, Atlantic and Monmouth Counties was held in Sea Girt, on July & to decide upon the location of the proposed ocean boulevard from the Highlands to Cape May City. A slight change from the originally proposed plan was made, the coast route from Mantoloking being abandoned and a curve out from there made to Burrsville, and thence by inside route to Toms River. The object of this change is to avoid an expensive bridge at Seaside Park. It is thought that the proposed boulevard will be used mainly by automobiles. and the delegates to the meeting were of the opinion that the burden of keeping it in repair should be borne by motorists. It was stated that an increase of 50 per cent. in the license fee would net \$100,000 additional revenue per year, and Governor Fort was urged to recommend such an increase in the license fee imposed on automobies

#### Everitt and Metzger Reported Backing New Million Dollar Company.

Romers have been current in Detroit that W. E. Margor, B. F. Everitt and William K. I., who some months ago withdrew from the Everitt-Metagor-Flanders Company, are clarified to regarde a new company and place upon the market a \$500 car, on the feed upon the market a \$500 car, on the feed upon the feed to that 25,000 of these regularity to be styled the E-M-K, are to be looked it is to be a 20 horse power register with a single rumble seat, and equipped with head, side and tail lights, bern and tool chest.

# Effect of Altitude on Carburetor and Motor Action.

Liditor Horseless Age:

My attention has been called to several unusual problems in automobile work, and I take the liberty of asking you to give me your opinion on same. Also, please inform me if you have ever published any answers to the following questions, and when:

Suppose I toured through the West in my car, built by an Eastern builder, and during my trip I arrived at the city of Denver. The altitude of Denver is, I believe, about 5,000 feet above the sea level.

No. 1. What effect would the lessened atmospheric pressure have on the carburetor's action? Could I remedy same, and how?

No. 2. Would the lessened pressure affect to any noticeable extent the work of the gas mixture in the cylinder?

No. 3. Would the explosive pressure be less by reason of the air being lighter and correspondingly smaller amount of oxygen per cubic foot?

No. 4. Would not the water by reason of its lower boiling point at this altitude permit the cylinders to become dangerously warm?

What arguments are advanced for or against the use of sub-frames upon which to place or suspend the power plant; that is, the motor and transmission gear?

E. B. GUTHRIE.

The effect of the rarification of the air at high altitudes on the carburetor is the same as that of a partial closing of the throttle valve. If your carburetor is an automatic one, it should give a substantially perfect mixture at all positions of the throttle, and should, therefore, also give a substantially perfect mixture at a considerable altitude, even though it is adjusted to work at ordinary altitudes. At an altitude of 5,000 feet above sea level the density of the air is decreased by about 17 per cent., and that much less air will be taken into the cylinder at each stroke. The explosion pressure and the work obtainable from each charge will be reduced at least in the same proportion. There is no danger of the cylinder becoming overheated by reason of the reduced boiling point of water. Owing to the fact that the cylinder takes in less charge at each explosion, the cylinder walls absorb less heat than where the atmospheric conditions are normal. The whole subject of the operation of gasoline motors at high altitudes was discussed in an article by Mr. Clough in THE HORSELESS AGE for June 27, 1906.

The chief argument in favor of the subframe for carrying the motor and change speed gear is that it protects these parts against the twisting strains due to the distortion of the main frame, so that there is less likelihood of the supporting arms on the crank case and gear case being broken or the cases themselves damaged. Another advantage is that the cases need not be cast with such long supporting arms, which are more or less troublesome, both in casting and in machining. The argument in favor of the method of supporting the engine and change gear directly upon the main frame is that it does away with an unnecessary part, which makes for simplicity in construction.—ED.]

#### Queries.

Editor Horseless Age:

Many thanks for the clear explanations given to some questions I recently asked in regard to the throttle and spark control. If you will kindly answer the following questions you will be doing me a great favor and incidentally settle some disputes.

- 1. On a four cylinder, 30 horse power car is it a safe practice to go down hills by cutting off the magneto, thus allowing the engine to act as a brake? If it is dangerous, why?
- 2. Last year on most of the cars that had the sliding gear I noticed that the application of the emergency brake also disengaged the clutch. This year I notice that a number of well known cars operate the clutch by the pedal, when last year they did it the other way. Can you give any reason for the change? Which way would you prefer?
- 3. I have a Bowser gasoline storage outfit, and the pump is fitted with two fine wire strainers. Do you think it is necessary to filter the gasoline through a chamois skin when filling my car? The Bowser people claim, of course, that the chamois is not needed, but I wanted to find out what you think about it. It takes so much more time to run it through a chamois that I do not want to do it unless I have to. G. W. C.

[There is absolutely no danger in descending hills with the magneto cut out and the motor acting as a brake; in fact, it is the best method of descending long, steep hills.

We do not know just what make of car you refer to in your second query. At one time it was a very prevalent practice to interconnect both brakes with the clutch so that the engine would be disconnected from the car before the brakes were applied. The advantage claimed was that the engine would thus be protected from the shock of braking, and another advantage would be that the car can be brought to a stop more quickly, as the energy stored up in the flywheel and other moving parts of the engine need not be dissipated by means of the brakes. But if the brakes are both interconnected with the clutch it is impossible to use the engine as an auxiliary brake. For this reason many manufacturers now compromise the matter and interconnect only one brake with the clutch, and others make both brakes independent of the clutch

As regards the necessity of filtering gaso-

line through chamois skin, after it has once been filtered through wire gauze, you can safely trust the instructions of the manufacturers of the storage outfit, whose experience in this matter is very large. Fine wire gauze will not pass sediment that is likely to obstruct your carburetor, and the water is usually separated by means of a gravity arrangement. That is, at the bottom of the strainer there is usually a settling chamber in which the water collects and from which it can be drained at intervals.—Ep.]

# General Motors Buys Cadillac Plant.

The General Motors Company has added to its manufacturing resources by the purchase of the factory and equipment of the Cadillac Motor Car Company, of Detroit, Mich.

The capital stock of the Cadillac Company is stated to have been \$1,500,000, made up of 15,000 shares of \$100 each. These shares are said to have been held as follows: William H. Murphy, 3,055 shares; Lem W. Bowen, 2,840; Clarence A. Black, 2,840; Albert E. F. White, 1,607; Union Trust Company, trustee, 1,607; H. M. Leland, 1,340; W. C. Leland, 1,340; E. A Leonard, 179; Ernest E. Sweet, 107; H. H. Pattee, 50; A. C. Leonard, 35.

The first offer made for the stock is said to have been 160, which was afterward increased to 200. The final purchase price is said to have been about 300, making the total paid in the neighborhood of \$5,000,-The strongest local report is that the deal was made on a cash basis, and carried through as a whole. There is a rumor, however, that General Motors agents bought stock quietly from individual owners until they obtained a controlling interest. As in most big deals, the public is at liberty to accept whichever version it likes best. W. C. Durant states that the management and policies of the Cadillac Company will be continued unchanged. W. C. Leland will remain as manager, with H M. Leland as adviser.

The fact that the Lelands retain the management of the Cadillac Company made it appear probable that they received stock of the General Motors Company in part payment for their Cadillac holdings, and rumor has it that they got \$100,000 of such stock. In this connection, the sharp fluctuations during the past several months in the price paid for this stock in Detroit are of some interest. Early in April it sold at about \$50 a share. In June the price was boosted to \$130 a share, but it was then stated that the stockholders were offered stock at \$100 a share. The result was a sudden drop in the price of the stock to \$107 the first week in July. Whether the acquisition of the Cadillac property will brace the market for G. M. stock remains to be seen. According to a report in a Detroit paper, the Cadillac Company has declared one dividend of 10 per cent. and one of 25 per cent. this year, 1909.

# Commercial Applications.

#### Rapid Fire Gun on Motor Truck.

The largest automatic gun in the world was tested recently at Cleveland, being the first Government test of a heavy rapid fire gun mounted on a motor car. A Packard 3 ton truck was used for the demonstration. Lieut, Col., O. W. Lissack, of the ordnance department of the United States Army, and Dr. S. W. Mc-Clean, designer of the gun, had charge of the tests, being assisted by the Standard Automobile Company, the Cleveland dealer for Packard motor cars and trucks.

The gun fired 3 pound shots at the rate of 100 per minute, the range being 3½ miles. Shots were tried with the brakes of the car set and also released. When the brakes were set the truck did not move and no shock was felt by those surrounding the gun on the truck platform. With the brakes released there was a slight movement on the recoil, but no shock. The designer of the gun recommends its use on armored trucks.

#### Wholesale Milk Delivery by Motor Truck.

The Plainfield Transfer Company is operating an automobile truck as a freight car between Indianapolis and Plainfield, the latter being about 20 miles west of Indianapolis. It is patronized almost exclusively by farmers who send their milk to the Indianapolis creameries, paying the transfer company 2 cents a gallon for making the haul. Farming implements and other articles purchased by the farmers in Indianapolis are delivered at the farmers' doors.

#### Commercial Notes.

An automobile line is in contemplation between Rome and Adairsville, Ga., a distance of 18 miles. Capitalists of Rome are said to be behind the project.

Dishmaker Brothers, of Kewaunee, Wis., a small department store, with a heavy rural trade, has purchased a runabout for canvassing and delivery in the country dis-

M. J. McDonald, 1084 N. High street, Columbus, Ohio, has ordered a number of taxicabs which he will operate in that city. The first of the cabs was to be delivered this week.

A. Lethoff, superintendent of the machinery departments of the string of sugar beet factories operated by the United States Beet Sugar Company, has purchased a four cylinder roadster, to cover his extensive territory in western Wisconsin.

Chief Thomas A. Clancy, of the Milwaukee (Wis.) Fire Department, will be

RAPID FIRE GUN MOUNTED ON MOTOR TRUCK.

the principal speaker at the annual convention of the Wisconsin Paid Firemen's Association, at Madison, Wis., on August 10, 11 and 12. His subject will be "Are Auto Fire Apparatus a Success?"

The Southern Railway Company is experimenting with automobiles for the transportation of passengers and hand baggage between Manassas and Strasburg, Va. The distance between these two points is 61 miles

The Nashville Taxicab Company, Nashville, Tenn., inaugurated its service with three cabs on June 29. The company has its offices and garage at 112 Third avenue South. James Frazer is president and Banks Bennie secretary and treasurer.

Manager Swift of the Swift Taxicab Company, Trenton, N. J., has resigned, and the business will in future be conducted by Nicholas Snyder, the principal stockholder, and Joseph Buch, manager of the Trenton House, under the name of the Trenton Taxicab Company. The company operates two machines and has a stand at the Trenton House. Two additional machines will shortly be placed in service.

A 2 ton gasoline truck has been purchased by the Indianapolis Brewing Company, Indianapolis, to be used in its city delivery work. Some years ago the company purchased a 5 ton electric truck but because of the enormous loads it carried it was barred from the paved streets. At present the electric truck is used for hauling between the brewery and freight yards. The Polk Milk Company, of the same city, has purchased a 3 ton truck, to be used in collecting milk through the rural districts.

A project is on foot for establishing an automobile service between Rosswell, N. M., and Monterey, a new town on the El Paso and Southwestern railroad, 100 miles north of El Paso. The town of Rosswell is willing to build the road from that city to the Lincoln County line, and if the authorities of Lincoln County will agree to build the road in their territory, the project will, no doubt, go through. Such a

line would greatly improve the mail service to twelve to fifteen inland post offices which now can only be reached on horseback.

#### Racing Drivers Killed.

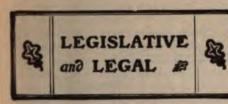

C. K. Batchelder, of Newport, Vt., and J. Twohey, of Montreal, were killed at the second annual races of the Canadian Automobile Club at the Blue Bonnets track on July 9. Batchelder was driving a 60 horse power car in the 10 mile open race for stock touring cars, and Twohey was his mechanic. When turning out to overtake another car Batchelder's 60 horse power car skidded and dashed into the fence, and the two occupants were thrown out. Twohey was killed instantly and Batchelder died shortly after his arrival at the hospital.

#### Minneapolis Representation.

Lindsay Brothers, an agricultural implement firm of Minneapolis, Minn., located at the corner of Fourth avenue North and First street, some time ago entered the automobile business by taking the agency for solid tire cars. They now wish to take on, in addition, a good car of standard type, that will appeal to the city trade as well as to country customers, they covering the country districts of five or six States. The firm is somewhat inclined toward cars that have been on the market for some years in preference to entirely new makes.

#### New Detroit Sales Company.

The Michigan Motor Sales Company has just been organized in Detroit to handle the Oakland and Welch cars. The new company will occupy the Fee Electric Garage, on Jefferson avenue, which is being remodeled to handle gasoline machines. The electric garaging will be carried on in the basement, which opens on the street level at the rear of the building. William A. Brush, who has managed the garage of the Standard Auto Company, for some time past, is at the Head of the new organization.

#### Recent Decisions.

ILLEGAL SPEED EVIDENCE OF NEGLIGENCE.

On a conviction of the owner of an automobile and his chauffeur for manslaughter in the second degree for colliding with a buggy on the highway, and causing the death of one of the occupants of the vehicle, who was injured by being kicked by the horse at the time of the collision, it was held that the owner of the car was not responsible where he did not contribute towards the accident. It was further held that there was sufficient circumstantial evidence to show that the buggy was struck by the auto, although there were no marks on the auto, and that reading to the jury the statute regulating the speed was not error, as driving at a speed prohibited by law was evidence of negligence and might have been so charged .- People vs. Scanlon, 117 N. Y. Supp. 57.

DRIVER AND PASSENGER OF HIRED CAR.

In an action for injuries resulting in the death of a passenger in an automobile run for hire, where the injuries were caused by negligence in operating a trolley car at an excessive rate of speed, it was held that the negligence of the chauffeur was not imputable to the passenger where it did not have, and exercise, control over the chauffeur, and that running a street car in excess of lawful speed was negligence.—Wilson vs. Puget Sound Electric Co., Wash. 101 Pac. 50.

TOLL ROAD PUBLIC HIGHWAY.

In a prosecution for a violation of the Wisconsin speed law in running an automobile at excessive speed on a public highway, it was held that a toll road within the corporate limits of a village, operated by a private corporation, was a public highway.—Weirich vs. State, Wis. 121 N. W. 652.

#### Taxicabs Enjoined from Cruising.

An attorney claiming to represent about 1,500 independent cabmen of New York city last week applied to the Supreme Court for an injunction restraining the New York Taxicab Company from picking up fares in the streets, except with those of its machines which have special public licenses. He alleges that the majority of the cabs owned by the company are licensed only to occupy stands in front of certain hotels. The city issues two kinds of hack licenses, one allowing the vehicles to pick up fares at stands which they are allowed to occupy by arrangement with the property owners in front of whose premises these stands are located, and the other allowing the cabs to be driven through the streets in search of fares. The latter class of cabs are distinguished from the former in that they are required to carry numbers on their

lamps, which the former are not required to do. The complainants allege that the New York Taxicab Company has public hack licenses for a few of its cabs, but the majority are operated from stands. However, they allege, the company has double sets of lamps, and whenever business on a stand gets dull the driver merely exchanges his unnumbered lamps for a set of numbered ones and sets out to pick up fares in the streets. It is further alleged by the complainants that some of the cabs of the New York Taxicab Company assume stand privileges in front of restaurants, etc., claiming that they are being held by a fare within the restaurant, but in reality only looking for fares.

A temporary injunction was granted by the court on July 10.

Proposed Milwaukee Ordinance.

The common council of Milwaukee, Wis., is working on an ordinance designed to supplement the State auto laws. It was originally introduced by Cornelius Corcoran, president of the council, more than a year ago, but since that time a number of important amendment have been framed. Cars must come to a full stop when running behind a street car that stops at a corner to permit passengers to alight or enter, until the car starts and all passengers are on the sidewalk or platform. Columns bearing red lights are to be established at street intersections to divide the traffic. A speed limit of 8 miles an hour is prescribed within a territory comprising about thirty blocks in the downtown business district. All unnecessary noises are to be eliminated. The original Corcoran ordinance contains a clause requirng all operators to be examined and licensed, but this provision will, it is expected, be removed as unnecessary and a hardship.

Columbus, Ohio, to Regulate Garages.

Fire Chief Lauer, of Columbus, Ohio, will introduce an ordinance at the next session of the city council which will provide that no garage shall be more than one story high and that the structures shall be built of fireproof material. "No smoking" signs must be displayed, and the storage and handling of gasoline are closely regulated.

Society of Motor Car Selling.

The Society of Motor Car Selling was organized at Detroit during the week preceding the start of the Glidden Tour. The membership comprises a number of men in charge of the advertising departments of automobile factories. E. Ralph Estep, of the Packard Motor Car Company, is president; George M. Davis, of the Pierce-Arrow Company, secretary, and Charles W. Mears, of the Winton Motor Carriage Company, treasurer. These officers, with two members, constitute the board of directors. A charter will be secured in a short time, and then headquarters will be established.

#### The Buffalo One Gallon Ton-Mileage Contest.

Last Wednesday, July 7, the Buffalo A. C. held its fuel economy contest, which was announced only a little more than a week previously. Each competing car was given one gallon of fuel and was weighed with all passengers on board, and the product of the distance traveled on this amount of fuel by the weight of the car constituted the score. The run started at I o'clock, with twenty entries, nineteen of which finished. The course was from the corner of Main and Goodell streets to the foot of the hill near Clarence Hollow, a distance of 161/2 miles. Herbert A. Meldrum, ex-president of the club, officiated as referee, and Laurens M. Enos was chairman of the committee in charge. A large number of enthusiasts witnessed the event. The chief honors of the event were carried off by S. G. Averill, who drove a 1910 Franklin car. He succeeded in driving his car, which weighed with load 2,948 pounds, 46.1 miles on the supply of one gallon of fuel, making his score 135,902. The tonmiles per gallon figure out to 67.95, which is by far a world's record.

The Franklin was an 18 horse power touring car which went through the competition without road stops or trouble. The course was slightly rolling, with grades of about I per cent., and on the outward trip there was a slight head wind. The roadway was first one of good asphalt, then in succession brick of indifferent quality, badly worn macadam, a stretch of good macadam followed by one of bad macadam, full of holes, and crossed by high crosswalks, and finally a fair piece of State road. In addition to capturing the general contest trophy the Franklin won the trophy for its class, which was for motor cars ranging in value from \$1,001 to \$2,000.

The results follow:

			Miles	
	. 1	Weight	. Cov-

# GARAGE

#### A Denver Garage Enterprise.

The Denver Omnibus and Cab Company, of Denver, Col., operate three large and distinct garages and showrooms in that city. The largest of these is at 1643 Court place, and is claimed to be the best equipped establishment of its kind in the West. The building contains four stories and a basement, and affords 32,000 square feet of floor space. The basement contains the heating plant, and is also used for the storage of cars out of commission. The third floor contains the machine shop, which is equipped with a variety of machine tools driven by electric motors. The equipment of this shop is said to have cost about \$5,000. This floor also has a body department. An air compressor is located at the back of the body department, and piping from this compressed air plant runs to all floors, a pressure of 150 pounds being constantly maintained. The fourth floor serves as a storeroom for parts of machines for sale and as a stockroom. The first floor is devoted to the sales department, of which department E. W. Swanborough is manager. The walls and ceilings of this floor are finished in pure white, and as this room has a great number of windows it is remarkably well lighted. The second floor is occupied by cars in regular use. A complete shop equipment is at the disposal of chauffeurs, and there are also lockers and a wash rack. The greater part of this floor, however, is taken up by the paint and varnish rooms. Lyman R. Stone is manager of the motor car department, and J. M. Kuykendall is proprietor of the establishment.

PLAN VIEW OF THE KAISER GARTEN GARAGE,

# The Kaiser Garten Garage, Coney Island, N. Y.

This garage was built to provide a place where the patrons of the Kaiser Garten, which it adjoins, may conveniently store their cars while dining or being otherwise entertained. It is located near Surf avenue on Twenty-fourth street, which is toward the Sea Gate end of Coney Island, and somewhat removed from the noisy part of the resort, where the many attractions which have made it world famous are grouped.

The building occupies a space 80 feet wide and 150 feet long. It is quite suitable for its purpose, and may be taken as an example of the type of garage building which can be erected for a comparatively, small outlay for material and labor. This is a necessary consideration, because of the transitory nature of the seaside garage business, which prohibits the investment of a large sum in a building used for only a portion of the year. The framework of the building is of wood, and about ten feet from each side there is a row of eight posts which

support the trusses for the roof. That portion of the roof over the central part of the building is of tar and gravel. Extending lengthwise of the building, under the eaves, there is a continuous row of swinging windows on each side, as shown by the sectional elevation. These windows afford ample daylight illumination and ventilation. The roof and sides of the lateral bays which adjoin the central space are of corrugated iron, and the front and rear of the building are of stamped metal arranged and painted to represent stone blocks. There is one entrance to the building and that is about 25 feet wide, ample for two cars to pass each other. The entrance is closed by two sliding doors, one of which contains a small swinging door. The floor of the entire building, with the exception of cement stand, centrally located at the far end, is of cinders and gravel, which have been packed hard by rolling. This floor material, while not as clean or sightly as concrete or cement, has advantages, because it will absorb the oil which drips from the cars, and atmospheric moisture, which is always present at the sea-

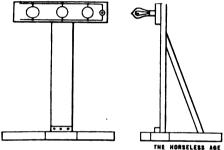

Two of the Garages of the Denver Omnibus and Cab Company.

side, does not condense and collect on it, as it does on concrete.

At the right of the entrance there is a small space partitioned off, which contains a desk and a couch for the use of the night attendant. This room is used as an office and storeroom, in which such parts as dry cells, shoes, tubes, carbide and canned lubricants are kept. Adjoining the office there is a workbench with two vises and an assortment of hand tools, it having been found inadvisable to install a machine tool equipment because of the small quantity of machine work which comes to a garage of this class. The management of the garage, however, also conduct a completely equipped repair shop conveniently located to Coney Island, where such repairs as come to the garage are sent.

Directly above the centre of the entrance there is a flaming arc lamp which affords ample illumination to show the painted Alpine scenery which adorns the top of the front of the building and causes it to harmonize with the surrounding decorations. The interior of the garage is illuminated by two Nernst lamps, which are suspended from the centres of the second and sixth roof

PORTABLE LIGHTING FIXTURE.

trusses, and furnish a soft, evenly distributed light, which is entirely satisfactory, because the annoying glare of open arc lamps and the uncertain illumination of incandescent lamps are absent. For brightly illuminating a car while it is being washed or repaired, the portable lighting fixture shown is used. It is a home made affair and consists of a T shaped upright of 3/x4 inch yellow pine, braced by a similar piece to the base, made of heavier stock, and arranged in the form of a cross. Three 32 candle power incandescent lamps are secured to the crosspiece as shown, and are wired to a plug socket which is adapted to be connected to the lighting circuit by a flexible cable.

Gasoline is stored in a buried tank located beneath a brick corrugated iron roofed house, which contains the pump connected to the tank. This house is removed about 30 feet from the garage and the space between it and the garage is enclosed by a fence, so that cars may be safely stored in this space in fine weather when the building is filled to its capacity of ninety cars. The usual system of checking the cars by means of duplicate brass tags, one of which is attached to the hand wheel of the machine by a leather strap and the other taken by the driver, is used here, and seems to be entirely satisfactory. The storage rate for transients is 25 cents for six hours or less for all days, with the exception of Saturday, Sunday and holidays, when the charge is 50 cents.

#### Garage Notes.

D. Harding, Madison, Ind., is erecting a garage on Post Office Square. He will do repairs. The Glide Motor Co., of St. Louis, agents for

the Glide car, have opened a salesroom at 3964 Olive street.

The Auto Trading Co., Cleveland, Ohio, recently opened a garage on Euclid avenue. They will specialize in the second hand car and livery business.

The Prince Wells Company, well known automobile dealers of Louisville, Ky., are reported to be negotiating with the Wright Brothers for their acroplane agency.

W. G. Redmon and E. L. King will open a garage in a new building, 34x80 feet, at the corner of Lexington avenue and Maple street, Winchester. Ky., about August 1.

McConnell & Clark, Cadillac, Mich., have recently occupied their new garage, which has a storage capacity for fifty machines and comprises a well equipped machine shop.

A new automobile garage of concrete construction, 50x100 feet, is being erected on East Front street in Florence, Col. The garage has been leased to a local automobile dealer.

Cuyler Lee, of San Francisco, agent for the Packard and Cadillac cars, has opened a branch office at 119 Telegraph avenue, Oakland, Cal. The new branch is to be in charge of R. E. Silver.

The Ferguson Parkway Garage, New York city. have bought out the Taxa-Auto Cab Company at 110th street and Central Park West. The building will be completely remodelled. J. A. Horwitz is manager.

The Los Angeles branch of the H. O. Harrison Company, Western representatives of the Peerless Motor Car Company, has been placed in charge of Thomas Williams, H. O. Harrison, formerly at the head of the branch, having gone to San Francisco.

E. N. Fowler, manager of the Palmer-Singer Company, is making arrangements to open an agency in San Francisco. The company expects to market part of the product of its factory on the Pacific Coast, which offers an excellent field for the sale of motor cars.

F. DeWitt and S. J. Mathews have leased the Armory Building, in Fort Clinton, Ohio, and opened a garage under the style of the Standard Garage. They have facilities for storing fifty cars and expect to take on a number of agencies. pair shop is conducted in connection with the garage.

The White Steamer Automobile Co., has leased the property at 26,33-2709 Wabash avenue at an annual rental of \$1,500 for the site, and 7 per cent. on the cost of the building, which is expected to reach \$120,000. The lease runs for twenty years. A four story reinforced concrete building is to be erected.

The Sheridan Motor Car Co., Sheridan, Wyo. have opened their new brick garage at Gould street and Grinnell avenue. The garage is 40x90 feet, two stories high, and will accommodate twenty cars. A machine shop is attached to the garage, which is in charge of James McGee. The company handles the White steamer.

After an existence of twenty years, the Indianapolis Transfer Co. has gone out of business in Indianapolis, to be succeeded by the Delaware Garage. Those interested in the new company include John E. Morand, formerly president of the transfer company. Others in the company are Cecil E. Gibson, of the Gibson Automobile Co.,

and C. R. Newby, formerly with the State Automobile Co.

The Abar Auto Company, Devil's Lake, N. Dak., have begun work on a new garage building.

#### New Incorporations.

Pullman Motor Car Co., York, Pa.-Capital stock. \$10,000.

Park Avenue Garage Co., Meadville, Pa.-Capital stock, \$5,000.

Speed Sales Co., Chicago, Ill.—Capital stock, \$40,000. Incorporators, Arthur W. McGovney, F. Rathje and H. Clay Calhoun.

Colonial Rubber Works Co., Chicago, Ill.-Capital stock, \$7,000. Incorporators, Henry Nyberg, Everett McConnell and Emerson McConnell.

The Delaware Garage Co., Indianapolis, Ind.-Capital stock, \$5,000. Incorporators, John E. Marand, Paul R. John and Cecil E. Gibson.

The Meiselbach Manufacturing Co., Milwaukee, Wis.—Capital stock, \$50,000. Incorporators, A. D. Meiselbach, S. Wallheim and L. W. Clough.

Panacea Springle Automobile and Electric Transfer Co., Winston-Salem, N. C.—Capital stock, \$125,000. Incorporators, Eugene Johnston and

Siegmund-Baylies Co., Chicago, Ill.—Capital stock, \$40,000. To manufacture and deal in motors and other merchandise. Incorporators, O. S. Baylies, E. H. Arnold and A. C. Noble.

#### Trade Personals.

John G. Utz has resigned his position with the engineering department of the Chalmers-Detroit Motor Co. It is reported that Mr. Utz will be connected with a company which is about to start the manufacture of automobiles.

The employees of the Bausch & Lomb Ontical Co., Rochester, N. Y., last week erected a bronze and marble tablet at the factory of the company in memory of Henry Lomb, one of the founders of the firm, who died a year ago.

E. W. Nothsine, of Flint, Mich., has been appointed manager of the St. Louis Buick branch, and assumed his new duties on July 1. Nothsine succeeded H. M. Blake, who went to Chicago to engage in a different line of business.

It is reported that Col. Albert A. Pope, head of the Pope Manufacturing Co., is seriously ill at his home in Cohasset, Mass. It is stated that his nervous system was nearly wrecked by the vicissitudes through which his firm passed several years ago, after the collapse of the bicycle boom.

Head Salesman Van Slyke, of the Iowa Automobile and Supply Co., has resigned that position, and accepted the sales management of branch of the White Co., Cleveland, Ohio, for the territory including Iowa, Missouri, Nebraska and Minnesota. Mr. Van Slyke will continue to make his headquarters in Des Moines.

#### New Agencies.

Toledo, Ohio.--Wm. Love, Packard, for northwestern Ohio.

Ottawa, Kan .- King & Filson, Cartercar, Cameron and Rider-Lewis.

#### Trade Literature Received.

The Randall-Faichney Co., Boston, Mass .-"Jericho, the Horn."

Wilmington Fibre Specialty Co., Wilmington, Del -Price list of fibre.

Packard Motor Car Co., Detroit, Mich.-Folder, "What a Truck Hauls, and How It Hauls It."

#### m i n o r mention

G. W. Hall is organizing a company in Lebanon, Pa., to manufacture a car known as the New Willar. The old factory of the Acme Motor Company at Twelfth and Warner streets is being considered for a location.

The R. L. Kenyon Company, of La Crosse, Wis., manufacturers of tops, accessories for motor cars and boats, and cushions, have decided to build a new fire-proof factory. Upon its completion the force of fifty will be increased to 100.

The Taft-Peirce Manufacturing Company, of Woonsocket, R. I., who have been doing contract work for automobile manufacturers for a number of years, have taken up the manufacture of motors for automobiles and expect to be extensively engaged in this line within the next few years.

In the State of Michigan 1,000 automobile licenses and 1,200 renewals of old licenses were issued during the month of June. On the last day of the month 60 new licenses and 128 renewals were issued. Under the present law, which will remain in force until the end of the year, the fee for licenses is \$1, and for renewals 50 cents.

According to R. S. Berry, representing the Ohio Oil Company, in an application to the Indiana State Tax Board for a reduction in the company's assessment, the oil producing firms find it difficult to dispose of the distillates of crude oil other than gasoline. There is a very large demand for gasoline, and that leads to an overproduction of the other distillates.

The General Motors Company, which has recently taken over the Northway Motor Company, at Maybury, Grand and Grand Trunk, Detroit, has decided to enlarge the plant of this company, where motors will be made for the cars turned out by the General Motors Company. It will also enlarge the Michigan Auto Parts plant, in Old Delray, where change gears are to be made.

The Brighton Beach track, near New York, which about a year ago was laid out in building lots, after the fences had been torn down, has been leased by the Motor Racing Association, which will hold a series of racing tournaments on it, starting with a twenty-four hour race, on July 30 and 31. The Racing Association will rebuild the fences and bank the turns so as to make high speeds possible.

The Atlanta (Ga.) A. A. on July I elected the following officers: Asa G. Chandler. president; F. J. Cooledge, vice president: W. D. Owens, treasurer and E. M. Durant, secretary. This is the association which is promoting the construction of an automobile race track near Hapeville, Ga., which is expected to be completed by

the first of November. At the meeting the dates of the fall automobile races were fixed for November 9-13.

The Sellers Motor Car Company, of Hutchison, Kan., shipped its first car on July 3 to Oklahoma City.

The Highway Auto Oil Company, St. Louis, Mo., has opened a salesroom at 4971 Delmar avenue, in charge of P. Spellen.

A new building is being erected at 3928-3830 Olive street, St. Louis, which is to house the local branch of the B. F. Goodrich Company.

J. G. Rodman, district superintendent for the S. F. Bowser Company, of Fort Wayne, Ind., has opened an office in St. Louis in the Chemical Building.

The Boston Park Department has purchased two Columbia cars for the use of Superintendent Pettigrew and the Engineering Department, respectively.

J. M. Quinby & Co., of Newark, N. J., have introduced the term "tonnette" as a substitute for the compound terms "baby tonneau," "toy tonneau" and "miniature tonneau."

The Regal Motor Car Company, of Detroit, started one of their 30 horse power cars from New York on July 5 on a transcontinental trip to San Francisco, which is to be completed in thirty days.

A petition in bankruptcy has been filed against the Commercial Battery and Electric Company, of Chicago. The liabilities of the concern are estimated at \$35,000, while the assets are valued at only \$5,000.

The officers of the New York and New Jersey Metal Trades Association and the National Metal Trades Association report that in spite of the business depression the automobile manufacturers had their busiest year.

The American Auto Brokerage Company have opened a second hand automobile and motor boat business at 3910-3912 Washington avenue, St. Louis, Mo. The company is composed of L. J. Winkler and M. W. O. Finlay.

Norman J. Rimes has purchased an interest in the J. M. Newsom tire agency and repair business, St. Louis, Mo. The firm name will be changed to Newsom & Rimes. The shop and office of the firm are located at 4142 Olive street.

Considerable damage was done to the plant of the Seitz Auto Transmission Company in Detroit on Friday of last week by an explosion in a neighboring plant. All of the windows in the Seitz factory were shattered and some of the machine tools were torn from their foundations.

Work of surfacing the outer and inner courses of the Indianapolis motor speedway is under way, and will be completed the latter part of July. Both courses are being treated to a coat of taroid, which is expected to give it a rocklike surface. It is expected that the work will cost \$40,000.

L. J. Kinnell, former agent for Mitchell cars in Joliet, Ill., has disappeared with the funds of the Kinnell Automobile Company, of which he was president. The

store where the garage was located has been announced for rent, and the stock of the automobile company has been confiscated and will be sold at auction.

Mrs. Harriet Clark Fisher, of Trenton, N. J., will sail this week for France, from where she will start in an automobile tour around the world in a 40 horse power Locomobile. A "bon voyage" luncheon will be given to Mrs. Fisher at the A. C. A., New York, on Friday at I p. m.

The Pietsch Auto and Marine Company, of Chicago, is planning to remove its plant to Kalamazoo, Mich. It is stated that the company has been established for three years, is incorporated for \$30,000, and has turned out about 500 cars (?). If the plan of locating in Kalamazoo goes through the capital stock is to be increased to \$100,000.

The Vanguard Automobile Supply Company, of Joliet, Ill., of which C. F. Jensen is president, is considering a plan to remove to Salem, N. Y. The business men of the latter town are offering the company the free use of a building, 160x75 feet, with good shipping facilities. The company claims that it has been unable to secure a suitable location at 'a satisfactory price in Joliet.

The Franco-American Taximeter Company have moved to spacious quarters on Seventh avenue and Forty-ninth street, New York City, from which point they will direct the entire business, which has hitherto been in charge of Lavalette & Co., as rental agents. The new building comprises a garage and extensive repair shops. The company has branches in Boston, Washington, D. C., Chicago, San Francisco and New Orleans.

#### Club Notes.

The Cambridge (Ill.) Automobile Association was organized at the Town Hall in Cambridge on June 22. All owners of automobiles and motorcycles in Henry County are eligible to membership.

Alfred Howard has been elected vice president of the Bay State A. A. of Boston, Mass., to succeed Harlan W. Whipple, formerly of Andover, Mass., who has recently taken up his permanent residence in New York city.

The Milwaukee A. C. has been advised that it will not be able to have the use of State Fair Park mile circular track for its annual meeting until after September 17, the closing day of the Wisconsin State Fair, and all plans for contests before that time have been dropped.

The Western A. C. has been organized in San Francisco, and has leased the Jefferson Square Building, at Golden Gate avenue and Octavia street, which it will convert into a clubhouse. The club has elected the following officers: Louis A. Mooser, president; Dr. G. R. Hubbell, vice president; Wm. V. Lloyd, second vice president; W. N. Wright, secretary and treasurer.

#### Sixth Annual A. A. A. Reliability Tour.

BY CHESTER S. RICKER.

DETROIT. July 11.-On the morrow will start the hardest, longest and probably the technically severest motor car contest that has ever been held. The departure of the competing cars will be made the event for a great celebration. The cars will start at 10 o'clock from the Pontchartrain, which is the official headquarters of the contest committee. It would seem from casual observation that almost every trade and press representative of note is present. As usual, everyone looks to F. B. Hower, the chairman, for everything, and he must be credited with being one of the hardest workers on the tour. E. L. Ferguson, the secretary and starter, together with M. C. Reeves, the chief of observers, is among the most industrious. Indeed, ever since Friday they could always be found engaged in checking in the cars or in assisting the technical committee. Charles J. Glidden, the donor of the chief trophy, has been one of the leaders. Among the other automobile notabilities present are President Lewis R. Speare, of the A. A. A.; Vice President Frank M. Joyce and Secretary F. H. Elliott. So many members of the trade are present that it would be futile to attempt to give a list of them.

Glidden Tours have been started with some pomp and splendor before, but it must be said for the Detroiters that they so outdid themselves that the men in charge of the tour either had to neglect their duty or stay away from the long list of festivities which had been arranged.

#### ENTERTAINMENT OF TOURISTS.

On Friday evening the Detroit Automobile Dealers' Association, which took a very active part in the arrangements for the preliminaries of the tour, and which was instrumental in securing the start of the tour for Detroit, gave a banquet to the officials of the A. A. A. at the Hotel Pontchartrain. About 125 motorists attended. The chief speakers of the evening were F. B. Hower and Charles J. Glidden. Mr. Hower expressed his disappointment at the small number of entries for the tour, and pointed out again the causes for the lack of interest among manufacturers. He said in part:

I was disappointed; all of us in the "Three A" were disappointed when we received so many refusals. We do not like to see the American manufacturers so wrapped up in their industry that they forget their sportsmanship. I can only say that we who have been behind this affair have done out best. The Detroit dealers came to me with \$3,000. They begged to have the start of the tour. I could not resist the temptation to give it to them.

If anyone had asked me at that time how many entries we would have I should have guessed about 125. We all guessed that. And then came the revelation. I began to receive letters from manufacturers all over the country. They found they could not enter the tour. The reason was that they were enjoying too much prosperity. They said, "Why should we enter this contest when we are unable to supply the demand now?

The advertising will do us no good." And so we have far fewer cars in the contest than we originally guessed.

I may tell you, gentlemen, that this auto business may be to the manufacturers an industry. To us who own and drive cars it is a sport. We are interested in these contests for the sport they offer. I do not say those manufacturers who made excuses were afraid of the sporting chance. I will not say it, gentlemen. That would be unfair to them, and so I will not say such a thing, but they did not enter, and I may tell you that we must keep up the sporting end of the industry if we wish to maintain the industry itself.

I shall be criticised, gentlemen, for what I am saying tonight. But I don't care. I am not here to promote the industry, but to promote the sport through contests. I say that those manufacturers who did not enter this tour hurt themselves, not us, for the Glidden Tour shows the progress of the automobile. Those who are unwilling to show what progress they have made are hurting the industry, not the sport.

Don't tell me that any manufacturer who could know he could win that trophy would refuse to enter. I will not call those who held out cowards, gentlemen, but there is not a manufacturer in the country who would refuse to join the contest could he know positively that he would be the winner.

The first speaker of the evening, Mayor Breitmeyer, presented Mr. Hower with a gold key to the city. President Speare then told how the farmer was making the automobile industry the power which it is in the prosperity of the nation. Charles J. Glidden then spoke and related his experiences during the years of touring which he has enjoyed. George C. Diehl then made a plea for good roads, especially aid in organizing a national good roads association. He made the statements that but 7 per cent. of the roads of the country are improved, and that without Federal aid the individual States can do little.

Hugh Chalmers next spoke on "The Automobile Industry—Not Game." He emphasized the necessity of the following qualities for the success of the business: Honesty, initiative, sincerity, openmindedness, enthusiasm. Benjamin Briscoe gave a short humorous address, but did not say much about the industry, as he was requested. Finally Colonel Pardee closed the evening with a clever little talk on the automobile and women.

President George Lane, of the D. A. D. A., was toastmaster. The great success of the banquet, as well as of the festivities which followed, is a great credit to the local Glidden Tour committee. The Detroit trophy, which is an exquisite piece of porcelain work, was officially handed over to the tour committee during the evening.

Saturday the following events were carried out most successfully: Automobiles conveyed those who desired from the Pontchartrain to the various factories. During the forenoon the executive committee of the A. A. A. met at the Hotel Pontchartrain. In the afternoon a big automobile parade took place. Also an entertainment was tendered to the executive board by the Auto Club of Detroit.

On Saturday afternoon, July 10, an auto parade was held in Detroit in honor of the Gliddenites, and proved to be the biggest thing of the kind ever arranged. There were 1,030 machines in line, over 400 of which were decorated. Many of the decorations were unique and beautiful. The parade started at the corner of Woodward avenue and the Grand boulevard, proceeded down Woodward to Jefferson, and along Jefferson to Belle Isle Bridge. Crossing the bridge it circled the island, the cars being parked at the southern end, where an immense group photograph was taken.

The prizes, so far as announced at the time of writing, were awarded as follows:

Sweepstake, Cadillac Motor Car Co. Lady's special, not announced.

COMMERCIAL FLOATS.

First prize, Vinton Co. Second prize, Morgan & Wright.

ELECTRIC CARS.
First prize, Anderson Carriage Co.
Second prize, Mrs. Eva Beecher.

GASOLINE OR STEAM CARS. First prize, in doubt. Second prize, Maxwell-Briscoe Co.

#### MOTORCYCLES.

First prize, lady in purple and green costume. Second prize, lady representing Columbia. Third prize, gentleman in leather suit. (Names not known.)

Attractive music was furnished by the Maxwell-Briscoe Band.

After the parade there was a series of athletic contests and ball games between teams from the local factories. While the parade was a striking success, in respect to the enthusiasm it aroused among Detroit motorists, only a small crowd went to the island to see the finish of the event.

Sunday the visitors were taken on the steamer City of Cleveland through Lake St. Clair and the Flats. Luncheon was served on the boat. Several members of the executive committee, as well as the representatives of The Horseless Age, were unable to take part in these festivities, because the technical examination of the cars was going on at the same time.

#### SOME STATISTICS.

Mr. Hower in recapitulation of the results of former tours made the following statement: In 1907, 98 miles per day average was required; in 1908, 132 miles per day, and this year, 1909, 180 miles per day average will be required. Also Denver and Kansas City have both raised an entertainment fund of about \$15,000.

GLIDDEN TOUR ENTRIES. 1907, 46; 1908, 30; 1909, 21. HOWER CONTEST ENTRIES.

1907, 13; 1908, 14; 1909, 14.
DETROIT CONTEST ENTRIES.
1909, 3.

Non-Contestants. 1907, 6; 1908, 10; 1909, 7.

OFFICIAL CARS.
1907, 5; 1908, 4; 1909, 4.

Total Entries. 1907, 74; 1908, 60; 1909, 46.

#### DETROIT TROPHY

Car No.	Name	Entrant
51	Am. Simplex	W. G. Isbell
52	Chalmers-Detroit	Jean Bemb
53	Premier	H. D. Smith

In addition to the regular competing cars, the following entries of non-contestants were made:

75—Rapid truck.
76—Press car.
77—Diamond Rubber Co.
78—B. F. Goodrich Co.
79—Studebaker, press car.
80—Studebaker, press car.
82—Maxwell, press car.
83—Chalmers, press car.
96—Acme, secretary's car.
97—E. M. F., confetti car.
98—E. M. F., pilot car.
99—Premier, chairman's car.

Nos. 77 and 78 are simply complimentary entries by the tire companies. No cars are being run.

#### OFFICIALS.

Following is a list of the officials of the contest:

Tec	hnical Committee:

Ioseph Tracy. Henry Souther. Owing to the fact that quite a number of the Western towns at which overnight stops are to be made are of only small size and offer only inferior hotel accommodations, it was decided by the committee in charge to make arrangements with the Pullman Palace Car Company for a train of Pullman cars to furnish meals and sleeping accommodation for the tourists at these points. The sleeping and dining cars will be side-tracked at the night stops from Fort Dodge, Ia., to the finish, and will accompany the tour for 101/2 days. Arrangements were made just before the start for six sleeping cars, three dining cars and a headquarters car for the officials and their outfit. Arrangements with individuals on the tour were made only for the complete service, at the rate of \$7.50 per day, which figured out to \$78.23 for each person for the entire number of days, which charge included breakfast, lunch, dinner and lodging. At Council Bluffs a baggage car is to be added to the train, for the accommodation of the tire makers who want to send along supplies. Although the sleeping and dining cars will be used at Council Bluffs, the headquarters will be at the Grand Hotel. The tourists will sleep in the Pullman berths, and will not only get their dinner at night and their breakfast in the morning in the dining cars, but will also receive each day a lunch put up in a box. It might be

GENERAL VIEW. START OF THE TOUR.

added that nothing was said about the charges for Pullman car accommodations until after the closing of entries, which was probably a wise precaution.

#### TECHNICAL EXAMINATION.

Under the heading of "Penalties," in the rules is found the following clause:

"At the close of the tour each competing car shall be delivered to the technical committee, which shall record all adjustments, replacements and repairs necessary to place each car in a safe and satisfactory operating condition. A card, bearing all details of the technical committee's findings, shall be delivered to the chairman of the contest board, one copy to the operator and one to the observer. The operator and such assistants as he may select shall then proceed to make the specified adjustments, replacements and repairs under constant observation by the observer, and shall be penalized, as hereinhefore provided, for time consumed and material and tools used. For the purposes of this rule the technical committee shall assume that each car was in perfect condition at the start of the contest."

Joseph Tracy and Henry Souther were to act as the technical committee. Unfortunately Henry Souther could not be present, and for a time it was thought there might not be an examination. Later, however, THE HORSELESS AGE representative was appointed a member of the committee protem, During Saturday and Sunday the thirty cars were examined. The examination was very carefully done by Mr. Tracy. The measurements taken were carefully entered on a blank sheet. Only one-half of this blank was filled out in Detroit, the other half will be filled out in Kansas City on the completion of the tour. Saturday Joseph Tracy and the writer made the examinations. On Surday, however, Messrs, E. L. Ferguson and W. C. Reeves came to

our aid and the cars were measured in much quicker time. The measurements take into consideration sag in the frames, flattening of the springs and bending or looseness in the steering gear.

#### WITHDRAWAL OF CARS.

The E-M-F entries were withdrawn and also the Stoddard-Dayton entries. The reason for the withdrawal of the latter was stated to be that it was impossible to prepare the 1910 models soon enough to get them into the tour, the company not desiring to put their old models through the tour. The E-M-F entries will go as non-contestants.

#### SPRING WRAPPINGS AND SHOCK ABSORBERS.

At a meeting Saturday night E, L, Ferguson, the secretary, stated that springs not already wrapped might be wrapped wo cord or tape. Also shock absorbers could applied if the cars were not already equipped. Several of the contestants to advantage of the opportunity and wrapp their springs. It was further added the the condition of the shock absorbers as spring wrappings would be ignored at the finish. This was confirmed by Mr. Howe at the first meeting tonight.

#### FIRST MEETING AT DETROIT.

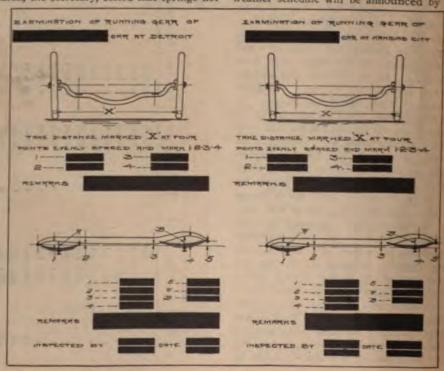

The first meeting took place at 8:30 of Sunday night. It was again stated the broken shock absorbers or windings would not be considered at the finish. Also the no work could be done on these para without penalty for work. However, if the equipment broke it could be removed desing running time without penalization.

Another ruling was that speedometer ould be repaired by the speedometer man at night controls with the chairman's permission. This was considered advisable, it was very necessary to know distances.

Last year penalties were imposed for hising outside aid in filling water, oil and galoline tanks. This year, however, anyone can do it for the driver. In case lamps is similar equipment get loose, no time work penalty is incurred if they are tightened in and the time is made up.

Contestants were advised that shovels are ropes could be purchased when desired, and it was insinuated that they might be needed. On coming to night controls passengers can be dropped before checking in. Likewise passengers can go to the control to standard or be taken up at the hotel, as the entrast desires.

Every night a bulletin will be issued giving the road conditions for the next days run. Also the running time for Class A If the weather is bad, however, the rainy weather schedule will be announced by the

starter. The running time for July 12 was seven hours ten minutes. It is raining, however, and road conditions may require slower time.

#### Detroit to Kalamazoo.

KALAMAZOO, July 12.-Sand, sand, sand was the cry of every one on arriving here after the day's run. The distance was not great, and the country was rolling, with scarcely a hill. On the other hand, it might be said that the cars were climbing a hill continually, so deep was the sand. In places the axles scraped the sand in the centre of the road. The writer was a passenger in H. O. Smith's Premier No. 1, with Webb Jay at the wheel. Except for a leaky valve on one tire the trip was uneventful. At Jackson we pumped it up and finally put in a new tube to save further trouble. This is the first time Webb Jay has driven since the accident to the White which he was driving two years ago. Without question, he is not only an expert driver, but a very careful one. Except for passing two vehicles on hills the entire run of 1423 miles was done on high gear.

We left the paddock at 10:06, being the sixth car to check out. The weather was fine, a little warm, perhaps, but pleasant when riding. It continued so through Jackson, but shortly after leaving there it became overcast. When we neared Cresco we encountered a slight shower, but later it cleared off and the finish was delightful.

The first to miles were over brick and macadam, but as good as these roads were, just as bad were those which followed. Except for a few intervening stretches through towns there were no good roads. The sand was deep, and the holes and ruts countless. Watching another car, one was reminded of the plunging of a boat in a heavy swell.

We passed both Brush entries Nos. 103 and 104, which had started just before us, about 6 miles out. Near Wayne two of the Studebaker press cars, Nos. 79 and 81, were passed. One had tire trouble from appearances and the other had stopped to help. By noon we were at Lima Centre, 49 miles out, and slightly ahead of a 20 mile an hour schedule which had been determined upon. Up to this point nothing had been seen of the three Moline cars, which had started first.

Just as we reached the brick pavement, entering Jackson, an announcer informed us that there was no speed limit, and from the small amount of traffic on the streets, as well as the crowd, it was evident that special provisions had been made for us.

#### LUNCHEON.

As in Detroit, we were royally treated in Jackson. The local chamber of commerce served each contestant with soft drinks and lunches, carefully put up in boxes. There was no doubt that every one was thankful. Gasoline, oil and water were supplied free to all who wished them. Thanks are due to the authorities of Jackson.

Cars Nos. 99, 100, 101, 102, 51, 1, 108, 109, 110, 8, 9, 11 came in within ten minutes. They were all following the chairman closely, and he was averaging about 25 miles an hour. During the afternoon there was a constant passing and repassing of the above cars.

Much interest was shown in the four small cars in the tour, Nos. 103 and 104, the Brush runabouts, 106, a little Hupmobile, and 110, the McIntyre buggy type of car. To the surprise of many the little Hupmobile had no difficulty plowing through the sand and keeping up with the largest company. Indeed, it checked in more than

an hour ahead of schedule. The big cars were a half hour ahead, and the little machine was with them. The Brush runabouts were on time and the only car late was the McIntyre.

Tire troubles were not much in evidence, considering the roads, except when the chairman had to stop for such. He soon had the tour going, however, when he did start. This year Chairman Hower keeps only a short distance ahead of the schedule and as a result little racing can be indulged in. It is very evident that every one is saving his car and not "driving it to death." Except for the McIntyre every car finished on time.

#### At Kalamazoo.

At 8:30 this evening, there was called the usual meeting of drivers and contestants. Among the questions discussed were the following: Several of the observers carried their baggage on the cars which they were coserving. Chairman Hower determined that they must carry it on their own official car.

Also in order to finish in the correct order the chairman requested contestants to use their slates. The finishing time must be chalked upon these at the start in the morning, and no car must overtake another

AWAITING THE START.

Nun	nber of running days, 15. Average miles per day, 175.8.		

on the road which is to finish ahead of it according to the schedule. He also emphasized the fact that he wanted a passing car to "keep-a-going" after passing another car, and not continue to throw dust in their faces. Besides, when a slower car is overtaken by a faster one, the slower must not increase speed, but must pull to one side.

When material is bought on the road a bill of memorandum must be shown by the observer and the driver. In case a fender iron is broken, as happened on one car, a penalty will be imposed for labor alone if a strap or wire carried on the car is used in the repair.

Announcement was made that the Chicago Motor Club would serve a Dutch lunch free, from 7 to 10, on the evening of the 13th. It was also announced that a speed trap was posted on Geoffery avenue. In a message from the Studebaker Company at South Bend it was stated that free lunch and low priced gasoline could be had by contestants. The running time for tomorrow is 8:40 for Class A. The distance is 173.3 miles.

#### PENALTIES.

Car No. 3, Chalmers-Detroit, I point for time required to fix fender and for cost of material used.

Car No. 104, Brush runabout, 6.8 points for a complete connecting rod bearing (to the credit of the little car it should be said that after losing 65 minutes on the road, it finished on time).

Car No. 110, McIntyre, 29 points for tardiness.

Tire troubles were experienced by Cars Nos. 1, 14 and 101. All but the three cars whose penalties are given above had perfect scores.

#### Kalamazoo to Chicago.

The second day's run, Kalamazoo to Chicago, was successfully completed by all of the thirty cars. The contestants were fêted both en route and upon their arrival in Chicago. When arriving in the latter city they were warned not to exceed a speed of 15 miles per hour on the boulevards. A detailed report of this day's run will appear in our next week's issue.

# Detroit Meeting of the A. A. A. Executive Committee.

At the monthly meeting of the executive committee of the American Automobile Association held on the morning of July 10 at the Hotel Pontchartrain, Detroit, the Wyoming State Automobile Association was elected to membership, thereby giving the A. A. A. its thirty-first affiliated State body.

President Louis R. Speare, of Boston, presided at the meeting. James R. Jackson, of Grand Rapids, Mich., and Col. W. D. Schier, of the Massachusetts State Highway Commission, were elected to membership on the good roads board, upon the nomination of Chairman Diehl.

A resolution was adopted conveying a vote of thanks to the Government officials who had extended courtesies to Chairman Evans of the touring information board, who is now in London attending the congress of the Ligue Internationale des Associations Tourists, which comprises all of the great automobile touring organizations of the world.

A membership committee of three, including Secretary Elliott, was authorized to investigate and approve of applications for individual membership, as well as applications of automobile clubs originating in States wherein there is no affiliated State body.

A vote of thanks was extended to the Detroit Automobile Dealers' Association and to the Automobile Club of Detroit for the entertainment provided for the association's officials and directors.

#### Huber Has New Small Car.

Emil Huber, of Davenport, Ia., was in Detroit at the start of the Glidden Tour, driving a small car of his own design. Mr. Huber has recently left the employ of 'the Meteor Motor Car Company, and expects to form a company in Davenport for the manufacture of his new runabout. The car has a four cylinder "block" motor, 'underslung frame, rather large wheels and a wheel base of 100 inches.

#### American Darracq Agency.

Henry Ducasse & Co., who recently acquired the American agency for the automobiles manufactured by A. Darracq & Cie., of Surennes, France, have opened an office at 737 Seventh avenue, corner of Forty-ninth street, New York city. They have established sub-agencies in Chicago, Boston. San Francisco, Washington, D. C., and Huntington, W. Va. They also have the Canadian agency for Darracq taxicabs. At present Messrs. Ducasse & Co. are devoting most of their attention to taxicabs, but they will shortly import pleasure cars and commercial vehicles also.

#### Foreign Notes.

According to a recent decision of the Belgian customs authorities, graphite grease intended for the lubrication of vehicle chains, put up in small steel cans, is dutiable as hardware at 13 per cent. ad valorem.

The output of rubber from the three rubber producing states of the Federated Malay States shows an increase of 60 per cent. for the first four months of the year 1909. The output was 1,577,325 pounds, as compared with 965,180 pounds for the corresponding period in 1908, an increase of 612,145 pounds.

No hill climb was held in connection with the Prince Henry Tour this year, because it has been found that in a drive up a serpentine mountain road (which sort of course was always selected in former years) the skill and daring of the driver is a much more important factor than the qualities of the vehicle.

It is reported that the French tire manufacturers, who are now members of three different trade organizations, are planning to join in a new Chambre Syndicale, an organizing meeting having been called at Paris for a recent date. It is rumored that the chief object of the organization is to pave the way for an increase in the prices of tires.

According to a recent ministerial order issued in New Zealand belt rims for motorcycles are dutiable at 20 per cent. when coming from any part of the British Empire and at 30 per cent. when coming from any other part of the world. Detached wheels for motorcycles are duty free when coming from any part of the British Empire and subject to a duty of 20 per cent. when from any other part of the world.

According to a recent consular report the importation of automobiles and motorcycles in British East India increased considerably during the fiscal year 1907-8. They are classed under the heading of wagons and vehicles. The imports under this heading during the year 1907-8 amounted in value to 1,595,000 rupees, as compared with 1,053,000 rupees the previous year. The bulk of automobile imports into India comes from Great Britain.

Kalamazoo

#### The Sixth Annual A. A. A. Reliability Tour-II.

By CHESTER S. RICKER.

#### Kalamazoo to Chicago.

CHICAGO, July 13.-To-day's run was accompanied by the same pleasant-though warm-weather which we enjoyed on the first day of the tour. It was the first day that any competing cars met with trouble sufficiently severe in nature to likely entail their elimination. The day's run was the longest so far, being 173.3 miles in length.

At 6:40 o'clock a. m. the chairman's car started, and 20 minutes later, exactly at 7, we left Kalamazoo. The writer again occupied a seat in the Premier car No. 1, which was driven by Webb Jay. Up to South Bend, 70 miles, our car led the way, and the run was delightful, especially as we did not have to take any one's dust. We were delayed somewhat in getting oil and water at South Bend, and in consequence were passed there by a number of

After leaving Kalamazoo we passed over about 30 miles of excellent dirt road, and had no difficulty in making this distance in one hour and fifteen minutes. From there on for about 20 miles the roads were an abomination, but fortunately they improved as we neared South Bend. After leaving South Bend, where the lunch stop was made, the roads steadily grew worse, until at Westville they were almost dangerous. To make things worse, the chairman stopped to try to extricate the Firestone truck which had become ditched a short distance before Westville. From there to the city limits of Chicago the roads were for the most part macadamized and in good condition, except for a half dozen miles,

where they were the roughest yet encountered. The dust finally became almost unbearable, but we had to stand it just the same. Almost three-quarters of the entire distance of the day's run was over improved gravel roads, and the average of the roads for the day was somewhat better than that of the previous day's route.

Chicago LAKE MICHIGAN KINDIANA STVILLE

The chairman held up the tour twice during the day. The first time he tried to help get the Rapid truck on to the road again, as it had gotten into a ditch in a swampy place. The second stop was made to replace a tire, and lasted only a few moments.

Some of the observers were much disgruntled by a ruling to the effect that every observer should change cars every night, and in the course of time serve on the cars of all the different entrants except the one who had nominated him. This was not satisfactory to the observers of the cars entered by the Pierce, Premier and other companies. The ruling was therefore changed so that the observers nominated by an entrant in the contest for one of the trophies need observe only on cars competing for that trophy. Thus, an observer nominated by an entrant of a Pierce car. in the Glidden Contest, for instance, need not observe on a Brush car competing for the Hower Trophy. This change in rules was announced by M. C. Reeves, the chief

At 7 o'clock to-night cars Nos. 104

(Brush) and 110 (McIntyre) had not yet arrived. Those reported as having had tire troubles were Nos. 5, 11 and 12. Cars Nos. 5 and 12 changed tires during running time, which is contrary to the usual practice. Car No. 3 (Chalmers-Detroit) had further trouble with its fender iron and stopped again to strap it more securely. As a result it incurred additional penalties, making the total number of points against it 1.4. Car No. 103 (Brush) lost 0.4 point for tightening up a loose front wheel bearing. The speed required is very high for the little cars and that they hold together is surprising. On this score the Hupmobile has already risen high in the estimation of the drivers of the large cars, as it keeps right up with these cars.

The Studebaker Company served an excellent lunch at South Bend, and supplied the contestants with oil and gasoline at

THE MARMON CONTINGENT,

AT THE START IN DETROIT.

THE JEWEL.

THE E-M-F PILOT WITH THE CONFETTL

moderate prices; it also provided water for those who wanted to replenish the supply in their radiators.

No official meeting was held in the evening, and this enabled the contestants to attend the pleasant affair referred to as a Dutch Lunch which the Chicago Motor Club had arranged in honor of the event. Besides serving an excellent lunch, the club gave an exhibition of moving pictures of the "Cobe Trophy Race."

So far the hotel accommodations have been very satisfactory, and not a word of adverse criticism has been heard. Glen A. Fargo and Geo. R. Rumney have full charge of both hotel and Pullman reservations.

Car No. 104 (Brush) finally arrived about 8 o'clock, and toward 11:30 the Mc-Intyre car, No. 110, put in an appearance. The writer was unable to find out what caused the delay of the Brush, but got a chance to interview the driver of the Mc-Intyre. His rear spring hanger broke at Decatur, Ind., and it took some hours to make a repair. After dark, he lost his road and in consequence was delayed considerably longer. Every one admired the grit shown by the drivers of the little cars. The running time for Class A for this day was 8 hours 40 minutes. For to-morrow, in the run to Madison, Wis., the time allowed for cars in Class A will be 8 hours 50 minutes. This class comprises cars listed at \$3,751 and upward. According to the rules, the time allowed for Class B (\$2,451-3,750) each day will exceed that of Class A by 10 minutes if the time for Class A is 71/2 hours or less; 15 minutes if the time for Class A is between 71/2 to 9 hours, and 20 minutes if the time for Class A is 9 hours or more. Similarly, the running time for cars in

Class C (\$1,751-\$2,450) will exceed that of Class A by 20, 30 and 40 minutes respectively; that of Class D (\$1,000-\$1,750) will exceed the time of Class A by 30, 45 and 60 minutes respectively, and that of Class E (less than \$1,000) will exceed the time of Class A by 40, 60 and 80 minutes respectively. The distance to Madison, Wis., is practically the same as that from Kalamazoo to Chicago, but the roads are said to be not so good.

The strain of riding all day, covering a distance of 200 miles, then getting to bed at 11 or 12 o'clock and up again at 4:30 to 5 in the morning is already making itself felt

Chicago to Madison, Wis.

Madison, Wis., July 14.-Today's run was the best we have had so far, and will probably not be equaled again for some time to come. The roads, of course, had much to do with this. So far as the large cars are concerned, the run was eventless, none of the big machines having incurred a single penalization. The smaller machines, however, have begun to feel the strain of the successive long daily drives. Car No. 110, the McIntyre motor buggy, had to drop out today. No. 104 (Brush), which was late at the night controls of the first two stages, did not turn up tonight. Car No. 106, the Hupmobile, is doing excellent work, invariably arriving at the night controls along with the large cars. Car No. 103, the other Brush runabout, also came in on time and apparently without trouble. Only cars 106 and 12 had tire trouble.

The penalizations of the Brush No. 104 and the McIntyre No. 110 up to July 13 were announced today. The McIntyre

broke a rear spring bracket and was penalized 423.7 points for lateness and 18.7 points for work. The Brush No. 104 lost 179.3 points for lateness and work combined. The bearing which gave trouble on the first day proved troublesome again on the second day, it was stated.

The running time for the third stage, from Chicago to Madison, was eight hours and fifty minutes for Class A cars. which did not call for any great efforts, considering the condition of the roads. The first 40 miles out of Chicago were macadam roads, which were oiled in many places, making them very pleasant to ride over. However, the speed regulations of the numerous towns passed through made it impossible to take advantage of these fine roads, and this continued all the way to Milwaukee. Except for a few hills near Evanston the roads were level all the way to Milwaukee. On our arrival there we were treated to an excellent lunch. Nowhere have we had such a pleasant noon stop, nor have we yet been more hospitably received than in this city. Gasoline was supplied free to all of the contestants, as was done at Jackson, Mich., on the first day of the tour. Most of the cars arrived at the noon stop behind schedule time, which indicated that the drivers were not taking any chances with the authorities, but af ter leaving the noon stop most of them kept up to the schedule for the next 30 or 40 miles.

Our day's run was 175.2 miles and necessitated an average speed of 19.6 miles per hour. Contrary to what occurred in the tours in former years, there has been practically no racing so far. Few of the cars ever get more than three-quarters of an hour ahead of running time, and this only to have time to take on gaso line and oil up before checking in at night. The driver of our car, Premier No. 1, has not experienced the least trouble in passing any car he desired. All that was necessary to do was to show the slate having our official finishing time chalked upon it, and in every instance the preceding car would allow us to pass immediately. Some of the entrants have already begun to realize that unless they know what class a car is in it is not good policy to follow it, because if the preceding car happens to be in a slower class they will soon find themselves behind the schedule.

The weather today was excellent. Although the sun was out it was somewhat overcast at times; and, besides, the greater part of the route was lined with trees, thus protecting the tourists from the direct heat of the sun. On the road to Milwaukee the juvenile element was extremely enthusiastic, but the older people did not show any particular signs of interest. Here and there some autoists had pulled up at cross roads.

After leaving Milwaukee the nature of the country, the roads and the people seemed to change abruptly. The roads were fine, although mostly made of dirt and clay. The route led through a beautiful farming region, and many summer hotels were passed, situated on the many lakes bordering the route between Milwaukee and the State capital. The cross roads were lined with farmers, and local motorists and town residents were out in

morning, and Mr. Hower recommended that each driver meet his observer on the previous evening. Another point to which attention was called was that all cars must check out at the parking station, and only there. The announcement made at Kalamazoo, that observers must not carry their baggage in the car to which they are assigned, was repeated here. There have

WISCONSIN

ACINE
A

full. At Marshall several girls handed out bouquets to the contestants.

Upon looking over the cars in the control upon our arrival in Madison the effects of the 490.8 miles traversed so far were hardly noticeable. The springs used on the cars seemed to be quite sufficient for the task imposed upon them, and no evidences of weakened springs could be found. One or two trunk racks are beginning to show the results of the strenuous work. Mudguard brackets have given trouble in two instances, the first car to suffer in this respect being No. 3, Chalmers-Detroit, and on today's run Car No. 12, Midland, had the same trouble. Neither car was penalized, however, as no work was done on the brackets. Car No. 103, Brush runabout, and No. 106, Hupmobile, had sprung leaks in their gasoline tanks. The latter seemed to have a leak in its radiator also. The perfect scores up to date are as follows.

Glidden Contest—Cars Nos. 1, 2, 4, 5, 6, 7, 8, 9, 10, 11, 12 and 14.

Hower Contest—Cars Nos. 100, 101, 102, 105,

Hower Contest—Cars Nos. 100, 101, 102, 105, 206, 107, 108, 109, 111, 112 and 114.

Detroit Trophy Contest-Cars Nos. 51, 52 and

The results of the tour so far establish a new record; that is, in no former contest have 86 per cent. of the cars come through the first 500 miles with perfect scores, and 93 per cent. in all.

#### At Madison.

No meeting was held at Chicago last night, so as to give the contestants a chance to attend the festivities provided by the Chicago Motor Club. The meeting this evening was short and to the point, and thoroughly characteristic of Chairman Hower. He scored the press cars for trying to cover both ends of the tour and all the space in between, they running by contestants with their mufflers cut out and at high speed. He especially emphasized the fact that he wanted the drivers to keep their muffler cutouts closed in passing through towns. He also insisted that the occupants of the cars should not throw any matches to the sides of the roads, as fires had been started in that way and complaints about the matter had come to him. The drivers were warned that they were responsible for getting their observers each

been frequent complaints by observers that the tonneaus in which they are required to ride are overloaded and that it is impossible for them to put their feet on the floor and to ride comfortably. Chairman Hower, therefore, ruled that in future sufficient space must be provided in the tonneaus to allow of the observers riding comfortably. Several complaints had also been made that drivers of cars, when others were trying to overtake them, increased their speed, and the chairman warned the contestants not to do this. He also said that some of the drivers seemed not to know which side of the road to take when others wanted to pass them.

At the close of the meeting the running time for tomorrow's run was announced as seven hours forty-two minutes for Class A. It was announced this evening that the McIntyre car, No. 110, had broken a wheel, and had therefore the full 1,000 points penalty imposed upon it; in other words, it was disqualified.

#### Madison to La Crosse.

LA CROSSE, Wis., July 15.—Today's run was marked by the worst roads which have been met with up to date. The first part of the day's route, immediately after leaving Madison, was comparatively good, and a fair speed was maintained by all the drivers. However, after leaving Baraboo, 42 miles out, the conditions changed slowly for the worse, the roads becoming exceedingly sandy, and at 79 miles we had to leave the main road and go through a grass grown lane. At the end of this lane came a hill which was so steep that many contestants doubted whether they could have climbed it if that had been required. Luckily for them, they had only to descend it. It, however, was only a sample

of the hills which we did have to go up. In two cases we passed over hills which the railway had tunneled through. So steen and rough were the roads that two cars were stalled and the entire caravan blocked. The time lost by the delay of necessity had to be made up, and with the very dangerous and rough roads following it was a miracle that any of the cars arrived on time. Scores. however, could not be announced, because the starter, Secretary E. L. Ferguson, was delayed. The reason for his delay was said to be that a child jumped into the road, and in order to save the child it was necessary to ditch the car. A front spring was broken and the front axle bent. Nothing further as to his whereabouts was heard up to midnight.

For four days now we have had perfect weather. Rain would have been very agreeable to the tourists this morning, as it would have laid the dust and made traveling a pleasure instead of a dust devouring trip. A shower did fall early this morning, but it was merely local, there having been no rain 6 or 7 miles out of town.

#### ALONG THE ROAD.

With such rocky and steep hills, abounding with water breakers, it is a wonder that many springs were not broken, and that tire troubles were not more prevalent. As on all previous days, the tourists struck a steady pace, which was little, if at all, faster than the schedule called for. As a result everyone lost still more time when the hills and rougher roads were met. As soon as these had been passed, about 30 miles from La Crosse, the contestants began to speed. The old racing spirit seemed to be rampant again, but it was a matter of necessity rather than of choice. Many of the cars did the 56 miles from the first bad hill to La Crosse in two hours, and this over roads which for 15 or 18 miles were beyond description, there being water bars every 50 feet or so, which, as our driver put it, were a yard wide and a yard high. About 5 miles from La Crosse. P. O. Bernhardt driving the big Jewel touring car No. 7, in the endeavor to make up time, took a turn so fast that the front tire was torn off, and Bernhardt finished the run into La Crosse on the rim. He had lost all his tools on the road and could not have changed the tire if he had wished to do so.

About 12 miles out of Madison the writer passed the Brush runabout No. 104, driven by Huss, with its hood off and the driver working on the motor. On the first long hill over the railroad tunnels Jewel No. 7, in trying to pass the Lexington No. 114, was stalled, and since the road was too narrow to permit passing, all the cars following were held up. More than twenty minutes were lost by this delay, which added still further to the necessity of racing.

SMALL CARS.

There was little expectation that the small cars would survive today's run. It is true that they suffered and were late, yet they

came through. The little Brush, No. 103, has always come in with the bunch, and usually only a little late. Today it did the same. The No. 104, Brush, driven by Huss, came in about 8 o'clock. The trouble was the same as that which caused delay on previous days, the crank pin bearing having to be rescraped. On the first day out Huss lost the scoop which is attached to the lower half of the connecting rod bearing and as a result no oil could reach this bearing. When the trouble was discovered the crank pin was badly scored. Since then Huss has smoothed the pin with emery cloth as best he could, and repeatedly scraped the bearing. As a result the car is doing better now than when it left Detroit.

Much regret was expressed at the nonarrival of No. 106, the Hupmobile driven by F. A. Stineman. The little car had a perfect score so far and was always in along with the big cars, although its schedule did not require it. Today it did not arrive until 10:10 p. m., and from all indications will not continue. THE HORSELESS Age representative was told by Stineman that the chief difficulty was the leaky radiator, which allowed the motor to overheat. During the day the clutch also stuck, and it was necessary to use the throttle and clash the gears when it was desired to change speeds. That the car got through under such conditions was remarkable. It will probably be withdrawn, and after a new low speed gear is installed and the clutch repaired the car may continue as a non-contestant.

#### OPINIONS ON DAY'S RUN.

Dai H. Lewis, in speaking with the writer, stated that he had never passed over such roads in his long experience as a path-

SPARTA

ner of the trophy would be determined by ballot.

#### CONDITIONS OF THE CARS.

Remarkable to say, there seems to be almost no trouble of consequence with the cars. The Midland had some trouble with its sod pan striking, so it was reported. Some difficulty was experienced by one of the Pierces in shifting gears, as an observer told the writer. Except for the breaking of a spring on the Acme No. 96, due to ditching, no spring troubles have been noticed. The Studebaker press car, when it was passed in Elroy, had a bolt out of the front wheel hub flange. The driver was endeavoring to put in a substitute. During the evening it was heard that he had broken this front wheel on a sandy road.

#### NO REPORTS.

As a result of the accident to the secretary's car and his non-arrival, no scores could be announced this evening. Nor was there a meeting of the contestants, as they were all so exhausted and only too glad to retire early. Up to date only the McIntyre No. 110 has been withdrawn. Car No. 106 (Hupmobile) will probably be withdrawn tomorrow.

Tire troubles were experienced today by cars Nos. 1, 11, 105, 111 and 114. Considering the road surfaces the cars were driven over the small number of tire troubles was astounding, but tomorrow will probably show the effects on the tires of the run today.

RUNNING TIME FOR TODAY.

Class A—7 hours, 42 minutes.

Class B—7 hours, 57 minutes.

Class C—8 hours, 12 minutes.

Class D—8 hours, 27 minutes.

Class E—8 hours, 42 minutes.

The distance was 154.4 miles.

La Crosse to Minneapolis. •
MINNEAPOLIS, July 16.—Another pleasant day greeted the tourists, and well might

finder and Glidden pilot. The pilot car was about an hour late, and it was thought by all that not a car would get through on time. When Dai H. Lewis went through on the pathfinding trip he took six days to make the run for which we were given seven hours forty-two minutes. It remained for the contesting scars to show how stanch and reliable American cars can be made.

was about an hour late, and it was thought by all that not a car would get through on time. When Dai H. Lewis went through on the pathfinding trip he took six days to make the run for which we were given seven hours forty-two minutes. It remained for the contesting scars to show how stanch and reliable American cars can be made. Charles J. Glidden stated that when such roads would not ruin the scores of the larger part of the cars the present purpose of the tour was at an end. Such was indeed the opinion of several other men interested in the tour. Mr. Glidden further stated that next year it was hoped to have the tour start from San Francisco and end at New York. No observers would be carried, and, as in the original tour, the win-

they be pleased, for had it been muddy it might have been a harder task than yesterday's run. The roads, although composed of dirt and clay, were free from the chuck holes which were found on the improved roads around Chicago. They were hard and smooth and made good running.

Today was the first day which in any

measure partook of the former Glidden Tour character. Every one profited by vesterday's experience and began to "burn up" the road from the start, so that in case bad roads were met later they could be taken with consideration. They were not encountered, however, and so the whole group of early starters arrived in Minneapolis right behind the pacemaker. As a result they were over an hour ahead of time. The Premier car, No. 1, in which the writer is riding, checked out first, and at Rochester came upon the chairman. stopped for lunch. When he started we followed just behind, and indeed stayed behind him all the way to the city.

The route led through the most beautiful country we have seen. During the morning we passed through some beautiful valleys, one just after leaving La Crosse and another after leaving Winona. Except for these two hills the roads led across the top of the hills and through miles and miles of beautiful fields of wheat. The views from the hills were magnificent.

ON THE ROAD.

The E-M-F confetti car was the first one to come to grief today. The roads were so smooth that the driver had almost forgotten that water breaks existed. About 118 miles out the car struck one, and before the driver, R. J. May, realized the whole car and party were in a wheat field. W. L. Conklin, who was distributing the confetti, was thrown from the car and had his ankle sprained. A rear spring was broken and the whole party was well scared. They continued, however, and finished in good time.

Scarcely anyone experienced trouble, except with tires. The only penalization announced was to Car III, the Jewel roadster. The air pump which raises the gasoline had to be worked on, and as a result the car was penalized for labor.

Many of the passengers were able to get a nap, the roads being so smooth, and the majority were in need of it, too.

#### AT NOON STOPS.

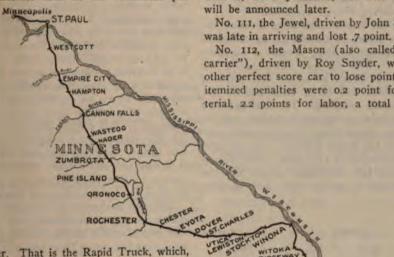

It is interesting to watch the contestants on their arrival at noon stops. As each car arrives there is a rush by the passenger for something to eat, both for the driver and himself. The observer is kept busy watching the oiling up of the motor by the driver, which is usually done at this time. The mechanic rushes for a supply of gasoline and endeavors to fill up the gasoline tank in half the time it really takes. Oil is poured into the crank case and lubricators, while someone else fills up the radiator. It is a mad rush, especially if the contestant happens to be behind his schedule. If not, he hurries in order to get away before those following, soas not to have to take their dust.

All the cars carry at least one Thermos bottle, and some more. Some prefer cold drinks and others hot. The usual lunch is a sandwich, if anything. Yesterday hardly any of the drivers stopped for anything to eat—they were so far behind their

ng time. Beer is the staple beverwhich is handed to tourists as they through towns. Most of the drivers ery abstemious, however.

THE RAPID TRUCK.

of the non-contestants is arousing interest than all the remainder put

er. That is the Rapid Truck, which, ng air bottles and tires, has been to make every day's run and has by earned much favorable comment. crew start early in the morning and y finish early in the evening, often dark. If the truck reaches Kansas and from all present indications it the manufacturers may well feel of its performance.

ENTHUSIASM ALONG THE ROUTE.

re genuine enthusiasm was shown tothan we have experienced before. village turned out in full to welcome ers. Groups of girls lined the roads tossed bouquets of flowers into the as they passed. The Western atmosof hospitality and good fellowship oming more and more evident as we arther West.

THURSDAY'S PENALTIES.

terday, as the secretary could not get Crosse during the evening, no anement was made with respect to the Indeed, Mr. Ferguson did not arantil 5 o'clock this morning. He exd that, besides having a broken they had lost their road several and traveled 40 or 50 miles farther. ing many side trips. The announcewas made this evening in Minne-

12, the Midland, driven by E. O. s, was penalized 3.7 points. The penvas divided into 0.6 point for material, meant a strap to lash the loose mud to the car, and 3.1 points as a time ty for time spent in fastening the and fixing the rod pan, which I unnd was struck by thank-ye-marms during the day's run.

104, the Brush, driven by Huss, was zed 343.9 points for late arrival and required by work on the crank pin, tightening a rear wheel bearing.

106, the little Hupmobile, driven by

Stineman, was late in arriving and was penalized 358 points. As the writer stated yesterday the Hupmobile will probably continue as a non-contestant.

No. 107, the Maxwell, driven by Goldthwaite, and No. 103, the Brush, driven by Trinkle, were penalized, but their scores

No. 111, the Jewel, driven by John Shimp,

No. 112, the Mason (also called "hod carrier"), driven by Roy Snyder, was another perfect score car to lose points. Its itemized penalties were 0.2 point for material, 2.2 points for labor, a total of 2.4

points. The trouble was with a pet cock in the cylinder, which broke and in consequence no power could be obtained. The driver showed great familiarity with his car, for he removed a radiator pet cock which would fit the cylinder and replaced the original. When the car arrived it was running excellently.

La Crosse

#### SCORES ON JULY 16.

Today few points were lost. The unfortunate were as follows:

No. 111, the Jewel, was penalized 0.2 point for material, 3.8 points for outside labor, and 2 points for driver's work, making a total of 6 points lost.

No. 106, the Hupmobile, driven by Stineman, was withdrawn, much to the regret of the contestants, as all the big car men were greatly impressed by the manner with which the little car had stood the gruelling

No. 109, no observer's card.

Nos. 103 and 104 were not in when scores were announced.

No meeting was held this evening.

RUNNING TIME OF THE CLASSES.

hours, 57 minutes, hours, 12 minutes, hours, 27 minutes.

#### Saturday at Minneapolis.

MINNEAPOLIS, Minn., July 17 .- The contestants in the tour, drivers, mechanics and observers, today enjoyed a well earned rest. During the forenoon they went on a trolley ride to Minnehaha Falls, and later they visited Fort Snelling, escorted by members of the Minneapolis A. C. At the fort a dress parade of the infantry, cavalry and mounted artillery troops was held, after which a reception was tendered the visitors at the officers' club. In the afternoon many of the tourists attended a horse race which was on the program among the entertainments. During the evening an automobile parade took place in which about 300 cars took part, many of them tastefully decorated. Following the parade there was an informal supper at one of the city's best known

Tomorrow the tourists will be taken to Lake Minnetonka, Dinner will be served at the Tonka Bay Hotel, and in the afternoon cars will take the men to the Automobile Country Club. The start from Minneapolis will not be made until eight o'clock on Monday morning, to allow the people of the city an opportunity to see the cars cross the line.

A new automobile cab company has been organized in Vienna, Austria, with a capital stock of \$150,000, and an order for 100 cabs has been placed with Laurin & Klement in Jungbunzlau, Bohemia. It is planned to begin the operation of the cabs this fall.

MAXWELL DRIVEN BY E. G. GRAGER PASSING THROUGH ELROY, WIS.

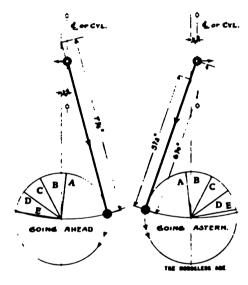

#### Tests to Determine Results Due to Offsetting Cylinders.

By JAMES McIntosh.

The offsetting of gasoline motor cylinders has been repeatedly discussed in the technical press, but I have failed to notice any instances of results of actual tests on the subject being published. I happened to be in a position to test the advantage gained by offsetting, and made a series of tests for my own benefit, the results of which may interest the readers of THE HORSELESS AGE. The tests were made on a single cylinder marine engine of the two cycle, three port, reversible type. In order to get uniform results I fitted the engine to run with natural gas, and with the spark set at D regulated the mixture to give the maximum speed obtainable with that spark adjustment, after I had warmed up the engine, regulated the flow of water to the jacket, and adjusted the cylinder oiler. For further precaution I started off with the spark set at A, the engine turning forward; then, with the spark still at A, I reversed the engine; then I moved the spark to B, keeping the engine turning in the reverse direction, then reversed it again so as to make it turn forward, with the spark still at B. In this way I continued until the end of the test had been reached, which was run without a stop from start to finish. The conditions at the moments of the various observations were, therefore, as nearly equal as possible, and the difference in the speed ahead and astern with the same spark lead will be twice the advantage gained by offsetting the cylinder, over an engine without off-

The engine here tested had only a 1/4 inch offset, the reason for making the offset so small being that the engine has to be reversed, which is not required in an automobile engine. The latter can be, and often is, offset much more, in order to reduce the side thrust of the piston on the impulse stroke, due to the angularity of the connecting rod. In my case the object sought was not so much to reduce the side thrust as to reduce the crank case volume and to ensure a low centre of gravity, the result of a shorter cylinder. By referring to the accompanying sketch it will be seen that with a connecting rod measuring 61/4 inches from centre to centre I have the same angularity as with a connecting rod measuring 71/4 inches from centre to centre in an engine without offset. This makes a gain of 1 inch in the length of the connecting rod, and the engine is, of course, correspondingly lower. On the other hand, when the engine is reversed the angularity of the connecting rod is the same as with the 51/2 inch rod in an engine without offset. While this angularity may appear to be excessive, I have not experienced any bad effects from this cause. In this connection it must, of course, be taken into account that the engine turns in the reverse direction only a very small portion of the time, and the advantage gained by offsetting while the engine is running ahead, owing to the reduced crank case volume and engine height, far outweighs any disadvantage due to the same cause during reverse operation.

It might also be interesting to know the relative values of natural gas as compared with gasoline as fuel. I made a comparative test with the two fuels, noting the maximum speeds at which they drove a two bladed fan direct connected to the crank shaft coupling. The fan had two radial blades measuring 63 inches over the tips, the blades being 10 inches wide radially and 3½ inches laterally. The fan arm had a thickness of 1½ inches. With natural gas as a fuel the engine would turn the fan at 830 r. p. m., while with gasoline

SPARE POSITIONS.

The spark positions given below represent the instant the contact is made at the commutator or when the spark coil vibrator starts to act.

A—Spark three-quarters inch late on 13 inch cir-

cle.

B—S; ark at dead centre on 13 inch circle.

C—S; ark 3 inches early on 13 inch circle.

D—Spark 6 inches early on 13 inch circle.

E-Spark o inches early on 13 inch circle.

MAXIMUM SPEEDS FOR DIFFERENT SPARK POSITIONS.

GOING AMEAD.	GOING ASTERN.
R. P. M.	R. P. M.
Spark at A 310	Spark at A 289
Spark at B 375	Spark at B 324
Spark at C 610	Spark at C 570
Spark at D 748	Spark at D 715
Spark at E 830	Spark at E 786

as fuel a speed of 1,100 r. p. m. was obtained. The difference in the horse power obtained with natural gas and gasoline, respectively, was, however, hardly a fair measure of the difference in the fuel value of the two fuels, for the reason that when the natural gas was used the charge was drawn through a spring controlled check valve, so that the opening was somewhat restricted, while the passage through the gasoline carburetor was large, which would naturally increase the speed.

In the comparative tests to determine the speeds of the motor turning ahead and astern respectively, I neglected the slight difference in the timing of the opening and closing of the ports resulting from the offsetting of the cylinders, and only considered actual speeds obtained for the different spark positions.

In conclusion. I consider that the advantages gained by offsetting cylinders are quite desirable, and where the engine is to be used in an automobile, where it is not to be reversed, a still more marked gain can be secured by employing a greater offset. However, where an engine is sold as reversible, it is well to limit the amount of offset, as serious damage might result during the reverse operation from excessive side thrust. Not only that, but the engine is harder to control when changing from reverse to forward operation, and is liable to cause trouble if care is not taken.

The tests were made on a single cylinder motor of 3¾ inch cylinder bore by 3½ inch piston stroke, having a connecting rod measuring 6¼ inches from centre to centre.

#### Fiat Decides on Poughkeepsie.

The Fiat Automobile Company has finally decided to locate its American branch factory in Poughkeepsie, N. Y. They have there obtained a site comprising about 30 acres, situated directly on the old Albany post road and only about 500 feet away from the Hudson River. The location was decided upon after considering offers from nearly 300 other points. The city of Poughkeepsie offered a private dock to become the perpetual property of the Fiat Company. This will enable them to make shipments by boat to New York and other points. Another inducement offered was the construction of a spur from the main feeder of the seven railroad trunk lines passing through or near Poughkeepsie. The site selected is in the northern part of the city and within twelve minutes' walking distance of the centre. An extension is to be made of the local electric railway as far as the new plant for the convenience of employees.

The parent Fiat Company, of Turin, Italy, will send their chief engineer, Chevalier Guido Fornaca, to this country during six months of each year to superintend the construction of the new models. In addition Engineer Marigny will be permanently located at the Poughkeepsie factory. Chevalier Giovanni Agnelli, the founder, and Ing. Enrico Marchesi, the commercial director, of the Fiat Company will make prolonged annual visits to the American plant. Albert E. Schaaf, who has long been connected with the American automobile industry, will be manager of the plant. Mr. Schaaf recently returned from a visit to the Turin works, where he studied the details of the organization and the manufacturing methods. It is hoped to be able to deliver the first cars from the American works in June or July of next year. Plans for the factory have been prepared, and it is expected that it will be ready for occupancy by the end of the year.

#### Mr. Hower's Speech.

Chairman Hower, of the A. A. A. Tour, is naturally disappointed that the tour this year is receiving such slight support from the manufacturers, but in venting this disappointment at the banquet given to A. A. A. directors in Detroit previous to the start he used rather ill chosen arguments.

One of the most significant—and, in our opinion, most fallacious—statements made by Mr. Hower was the following: "We must keep up the sporting end of the industry if we wish to maintain the industry itself." In other words, Mr. Hower holds that the automobile industry has no other foundation than the automobile sport. The future of the industry would, indeed, hold out little promise if this were true—if the sale of automobiles depended solely upon the interest of the public in races, hill climbs, endurance trials, etc.

Recently comparisons have repeatedly been made between the bicycle industry and the automobile industry, and the view has invariably been expressed that the latter would never meet with such a severe reverse as the former did. Although the line of argument has seldom been very clear, we

take it that the conclusion is based mainly on the well founded assumption that the field of useful application of the automobile is wider than that of the bicycle. As to the sport, there can be no manner of doubt that automobile contests in the course of a few years will be as extinct as the bicycle sport is now. There may still be "a match pulled off" here and there, and a few of the sportively inclined may risk their shekels on its outcome, but the great body of the public will be entirely unmoved by such events. If, as Mr. Hower asserts, we can only maintain the automobile industry by keeping up the sporting end, the industry would be doomed to an early demise. It will simply be impossible to keep up the sporting end, the public being altogether too fickle in its attachment to different sports.

The use of automobiles for pleasure driving is not sport. No one would maintain that the farmer who takes a buggy ride on Sunday is engaged in a sport. The term "sport" involves the element of competition. The use of automobiles for pleasure driving, irrespective of all considerations of sport, has become an established practice. Besides this, there is also the wide field of application of the automobile in commercial work.

There is no reason why the use of the automobile for legitimate pleasure driving should ever diminish. The number of people who can afford to keep a pleasure vehicle is constantly increasing, and the automobile is still being perfected and made constantly more superior to other pleasure conveyances. The field of commercial work is also constantly widening and will continue to do so.

The only branch of the automobile movement that is bound to be ephemeral is the sport. Sporting events are the means of creating a false interest in automobiles and of inducing numbers of people who cannot afford them to buy them. The multiplication of sporting events, no doubt, has the effect of temporarily stimulating the demand for automobiles, but who is to be benefited thereby? Certainly not the conservative manufacturer who constitutes the backbone of the industry, nor the capitalist who has money invested in it. There are only two classes of individuals who will be benefited by "keeping up the sporting end," viz., the sport promoter and the company promoter. The latter takes advantage of the artificially created, mushroom-like market to unload watered stock on the public, and the sport promoter, therefore, plays directly into his hands.

If we wish to maintain the industry, give it stability and permanence, and make it a promising field for investment by conservative capitalists, instead of keeping up the sporting end we must drop it altogether as we proceed.

#### Air Jacketing of Motors.

Several years ago a considerable number of engineers took up a form of cylinder cooling by forcing an air blast from a ventilator through a jacket covering the cylinders. The method was exemplified in a car which then occupied a somewhat more prominent position in the market than now, and its characteristics seemed to appeal strongly to the engineering world. Owing, however, to the disfavor with which the general public began to look upon the air cooled motor about that time, those who intended to bring out motors with air jacketed cylinders were unable to secure the necessary financial backing, and this cooling system has continued to be a feature of a solitary make of car in this country. That it possesses real merit may be inferred from the fact that it has just been adopted by the manufacturer having the most extensive experience with air cooled motors. A deviation from the previous system consists in the use of a flywheel fan in place of a blower.

It is not difficult to recognize a number of distinct advantages in the air jacketing system over the conventional method of cooling by means of exposed circumferential flanges, either with or without a fan. Where a fan is used, as is absolutely necessary with air cooled vehicle motors, a considerable proportion of the air moved by it goes astray and never strikes the cylinders. In this connection it is apropos to mention that there are some buggy motor designs of the double opposed air cooled type with flywheel fan in which the cooling effect must be almost entirely confined to the crank chamber. The jacketing of cylinders and the circulation of air through the jacket undoubtedly admit of, a higher degree of efficiency of the air circulation. That is, more heat units should be abstracted from the cylinders per unit of power consumed in driving the fan or ventilator. It should also be possible to better distribute the cooling effect. Where a blast of air is directed from one end against a four or six cylinder motor, it is obvious that the cooling effects on the different

cylinders cannot well be uniform, even though the radiating flanges may be differently spaced on the different cylinders to secure this object. With an air jacket the application of the cooling blast to the hot surfaces is accomplished in a much more rational manner. The cold air first strikes the head of the cylinder, which absorbs the greatest amount of heat from the burning gases. As the air becomes heated, and therefore a less effective cooling agent, it passes over the inner end of the cylinder wall, which requires less cooling. As to distributing the cooling effect between the different cylinders, this should be a matter of no difficulty.

Perhaps not the least advantage of the air jacketed cylinder over the exposed flange type resides in its smooth and relatively cool outside surface. The flanges of the conventional air cooled cylinder cannot well be finished, as no form of paint or enamel would long withstand the temperature to which these flanges attain. On this account, and also because the flanged surface is hard to clean, air cooled motors generally present a dirty, neglected aspect. The fact that on account of the high temperature it is impossible to wipe or otherwise clean a flanged cylinder while the engine is running, and for some time after, has also something to do with this neglected appearance.

The air jacket system should therefore make it possible to cool a motor more uniformly and with less expenditure of power than the conventional system, and should make a neater looking engine, easier to keep bright and clean.

# Taxing Fuel for Use in Pleasure Vehicles.

A tax upon gasoline used for motor vehicle fuel is being advocated in England and in certain Continental countries as being the probable source of considerable revenue, and as constituting a tax the incidence of which would fall mainly upon well to do persons. These proposals usually contain a provision by which gasoline used in the propulsion of commercial vehicles shall pay a less rate than that used in pleasure vehicles, or shall be entirely exempt, so that the burden shall not be seriously felt by business interests.

So far as the incidence of the tax is concerned there should perhaps be no serious objection from the standpoint of the political economist, but it would seem that there might be serious difficulties in pre-

ng evasions, as the enforcement of a

tax upon a commodity when used for a specific purpose only is ordinarily a difficult matter.

So long as the tax imposed represents only a reasonable percentage of the value of the gasoline, it would probably have but a slight effect upon the automobile industry, for the cost of fuel is not yet by any means the major item in the cost of operating a pleasure car.

Raising the cost of gasoline by imposing a tax might, however, tend to drive motorists to the use of untaxed fuels, if their application presented any economic advantages as compared with taxed gasoline. Increased cost of fuel arising from any cause tends toward the development of economical methods of using it, and a gasoline tax might thus be expected to stimulate research and invention in the direction of fuel economy.

The motor car is still regarded by the masses as the vehicle of the rich, and as long as this view prevails taxes of various kinds which bear upon it will continue to be proposed by legislators who are seeking popular approbation.

# The Increasing Satisfaction Given by Pneumatic Tires.

The recent rather general reduction in the weight and power of new models has done more to reduce the cost of operation than is generally appreciated, for in addition to the saving in mechanical items there has been a great saving in tire maintenance. Indeed, on some of the recent small cars the tire expense seems to be merely nominal compared with the figures for the larger machines.

The manufacture of tires for large, heavy machines made necessary a careful study of tire structure, for the best combination of rubber and fabric which can be produced is taxed nearly to the limit of its strength in supporting the weight of a heavy, rapidly moving vehicle against road shocks, and at the same time transmitting the torque of a powerful motor. The experience gained in the manufacture of large tires has naturally been incorporated in the smaller sizes, and has resulted in the longer life and greater freedom from trouble just mentioned.

It is comparatively easy to get tires for the smaller machines which are somewhat stronger than they need be to give satisfactory service, and when these extra large tires are placed under a car they are often remarkably long lived. The use of larger tires has wisely been encouraged by the tire manufacturers, who have brought out intermediate sizes which fit the next smaller size of rim. Thus a 30x3 inch tire may be replaced by a 31x3½ inch, or a 32x3½ inch by a 33x4 inch.

The standard tire equipment of low priced cars is almost invariably the standard size which the tire manufacturer recommends, but provisions are made in the clearance of mudguards, brake connections, etc., and in the clearance for swinging the front wheels for the special size of tires. These larger tires are furnished at an extra price, and the car agent is always ready to recommend their adoption.

That the public is educated to the wisdom of paying a little more for tires at the start to secure longer life and greater freedom from trouble is evident, for we notice that a goodly portion of the moderate priced machines are fitted with the special sizes.

Judging from what users of recent light cars have to say about the infrequency of punctures and the generally satisfactory service given by the later tires, there is less excuse at the present time for adopting solid tires on pleasure cars for use over ordinary roads and streets. Under such conditions the solid tire is probably not much cheaper to run than the pneumatic, which latter gives considerably greater satisfaction, since it makes it much easier to keep the car from rattling.

There are, of course, certain classes of service and certain kinds of roads where the solid tire presents many advantages; but for the conditions we have mentioned we think that it is not too much to say that the pleasure vehicle tire problem is quite satisfactorily solved by the present day pneumatic.

#### Coming Events.

July 31—Kansas City (Mo.) Race to Elm Ridge Park, Kansas City A. C. July 31—Richfield Springs Hill Climb.

August 5—Algonquin (Ill.) Fourth Annual Hill Climb on Algonquin and Perry Hills, Chicago

August 17—Cheyenne, Wyo., Track Meet, A. C. of Cheyenne.

August 31 or September 30—Milwaukee (Wis.) Annual Orphans' Outing, Milwaukee A. C. September 6-11—Lowell (Mass.) Annual Motor Carnival. Lowell A. C.

September 15—Denver (Col.) Start of Flag-to-Flag Race to Mexico City, Denver M. C.

October 7—Philadelphia (Pa.) Second Annual 200 Mile Stock Chassis Race in Fairmount Park, Ouaker City M. C.

November 6 to 13—National Automobile Show under the auspices of the N. A. A. M. at Atlanta, Ga.

December 29·30—Philadelphia (Pa.) Annual Midwinter Endurance Contest, Quaker City M. C. December 31 to January 7—New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

#### The Taxicab Business in New York City.

BY JOSEPH A. ANGLADA.

Within the past year the number of taxicabs operating in New York city has increased from a bare 100 to over 1,800 cabs. About 50 per cent. of the cabs now operating are the products of French factories, while the balance, with the exception of about eighty British cabs and twenty from German factories, were built in this country. About 90 per cent. of the taxicab business is in the hands of companies operating from six to 600 cabs.

Taxicabs plying in New York city must be licensed by the municipal authorities. An annual fee of \$10 is charged for each private or public vehicle, a private vehicle being licensed to operate from certain cab stands, and a public vehicle to solicit patronage at any point, except private stands. The public vehicles are designated by the municipal license number displayed on the front of the oil lamps carried. Taxicab drivers are also licensed annually upon the payment of a fee of \$2. The maximum legal rates are fixed by a city ordinance which makes a distinction between two and four passenger vehicles. Most companies, however, charge the same for one or four passengers, and the ordinance states that "all rates of fare shall depend upon the number of persons which each vehicle is intended to seat inside, and not on the number of passengers actually carried."

The standard rates fixed by the law, which goes into effect in October, are 30 cents for the first half mile or part thereof for two passenger cabs, and 40 cents for four passenger cabs; for each additional quarter mile or part thereof, 10 cents for both two and four passenger cabs. The charge for waiting is \$1 per hour for two passenger cabs and \$1.50 for four passenger cabs. There is no charge for hand bags, dress suit cases or children under five years of age; but for each large piece of baggage a charge of 20 cents is made. One of the large companies has, however, just announced a new schedule of 30 cents for the first half mile and 10 cents for each additional quarter mile for four passenger cabs. The former rates of this company were 50 cents for the first half mile and to cents for each additional quarter mile. It will, therefore, be interesting to learn whether this company will be followed by others in the reduction of rates below those fixed by law.

The majority of the taxicabs in use have inside accommodations for four passengers. Two are carried on the rear seat and two on folding seats attached to the doors or to the back of the driver's seat. Many of the cabs which have been placed in service within the past three months have but one front seat, used by the driver, the adjacent space being used for carrying trunks, and in some cases a folding seat is provided for a fifth passenger, but it is seldom used. In addition to the following operating com-

panies there are close to 200 taxicabs operated individually by their owners, who in many instances were chauffeurs who realized the possibilities for profits in the operation of taxicabs, and, therefore, secured a small car, generally second hand, and had it fitted with a suitable body and taximeter. In addition to these owners there are others who have fitted taximeters to their regular hacking cars, besides small companies operating from two to four cabs and from whom the writer was unable to obtain reliable data relative to their operation.

# THE CARNEGIE HILL LIVERY AND MOTOR COMPANY,

with offices and garage at 109 East Eightysecond street, operates ten Thomas cabs, and in the fall will increase the number to twenty. The cabs are operated from four stands, located at the stable, 2 West Ninetieth street, 4 East Sixtieth street, and 15 East Thirtieth street, respectively. Pneumatic tires are used and spare wheels are carried as reserve. Rates are standard, and in addition to the regular stand business some of the cabs are operated on monthly contracts with individuals. The taximeters are driven from the front wheels, and most of the repairs to the cars are made in the company's shop. A maintenance contract for one year is in force with the manufacturers of the cabs. The company also has a maintenance contract with the tire manufacturers. The average distance traveled daily by each cab is 60 miles. Operators are paid a regular salary, and gasoline and oil are furnished free by the company. The company states that in winter the busiest hours are just before the opening and after the closing of the theatres, while in summer the afternoon is the busiest time of the day.

## THE KAYTON TAXICAB AND GARAGE COMPANY.

with offices and garage at 182 East Seventythird street, operates twenty-six Atlas cabs, and states that this number will be increased to sixty-six on or about the first of October. The cabs are used in hacking and stand business, with stands at the Hotel Webster, Burns' Restaurant, Sixth avenue and Forty-fourth street, and the Hotel Bristol. Pneumatic tires fitted to quick detachable rims are used as standard equipment, and while at present the company does not specialize in conducting private services, cabs may be obtained for lengthy trips. The taximeters are driven from the front wheels and all repairs to the cars are made in their own shop. There is no maintenance contract between the manufacturers of the cars and the company, but a maintenance contract on a mileage basis is in force with the tire manufacturers. Fortyfive miles is the daily average of each cab, and the operators are paid a regular salary. Gasoline and oil are furnished free. In win-

ter the busiest part of the day is between 6 and 10 p. m., and in summer from 4 to 10 p. m.

THE MASON & SEAMAN TRANSPORTATION COMPANY.

with offices and garage at 200 West Seventy-seventh street, at present operates 197 cabs, 150 Delahaye, 40 Pilain and 7 Locomobiles, which number will be added to as the growth of the business warrants. These cabs are not used in a regular hacking service, but in a private livery service, and are operated from the following stands: 173 West Eighty-ninth street, 218 West Fiftieth street, Seventy-eighth street and Park avenue, Seventy-seventh street and Amsterdam avenue and the Park Avenue Garage, between Sixty-third and Sixtyfourth streets on Fourth avenue. Standard clincher pneumatic tires are used, and the taximeters are driven from the front wheels. All repairs are made in the company's shop, and while there is no maintenance contract with the makers of the cabs the tires are guaranteed for 5,000 miles. The drivers are paid a regular salary, in addition to a commission, and are furnished with gasoline and oil free of charge. This company caters especially to private trade, and to charge accounts. Excepting special events, the busiest hours are from 9 a. m. to 1 p. m.; 2 p. m. to 6 p. m. and from 7 to 12 p. m.

THE MOULTON STABLE COMPANY.

with offices and garage at 828-830 Seventh avenue, operates fifteen Thomas and ten Delahaye cabs at present, but will add to this number in the fall, the number being determined by the increase of business. A regular hacking business is conducted from the Hotel St. Regis, Hotel Gotham, University Club, New York Athletic Club and the Criterion Club. Cabs are fitted with pneumatic tires and spare wheels. While no special services to pleasure resorts are conducted, an extensive business is done in this line. All repairs are made in the company's shop and a maintenance contract for one year is in force with the Thomas Company. The tires are not maintained under contract by the tire manufacturers. The operators of the cabs are paid a regular salary of \$2.50 per day, and gasoline is furnished them free of charge. The busiest hours of the day at all seasons are from 5 to 12 p. m.

THE NEW AMSTERDAM MOTOR COMPANY, with offices and garage at 152 West Fifty-sixth street, operates eighteen Crawford taxicabs and twelve Crawford touring cars. A regular hacking business is being conducted, the company having no fixed stands. The cars are fitted with pneumatic tires and quick detachable rims. The standard rates are charged for both the cabs and touring cars, the latter being usually engaged for extended trips to pleasure resorts and country places. The taximeters are driven from the front wheels. All repairs are made in the company's shop. A

maintenance contract is in force with the manufacturers of the tires, but not with the manufacturers of the cars. The daily average distance covered by each machine is 35 miles. The operators are paid a percentage of the earnings of the car. Gasoline and oil are furnished free. In the winter the busiest hours are between 6 and 8 p. m., and in summer the business is practically the same at all hours of the day.

THE NEW YORK TRANSPORTATION COMPANY. with offices and garage at Eighth avenue. Forty-ninth and Fiftieth streets, at present operates 493 cabs, comprising 400 Columbia electrics, 53 Delahaye cabs and 20 cabs of miscellaneous makes. At present there are 250 De Dion-Bouton 14 horse power, four cylinder cabs on order, the first shipment of which will be received by September 1. The business is conducted from stands located at Sherry's and Delmonico's restaurants, Fifth avenue and Forty-fourth street; Café Martin, Fifth avenue and Twentysixth street; Hotel Belmont. Park avenue and Forty-second street; Hotel Astor, Broadway and Forty-fifth street; L. I. R. R. depot, foot of East Thirty-fourth street; Central R. R. of N. J. depot, foot of West Twenty-third street, and several hotels and clubs. Solid tires are used on the electric cabs and pneumatic tires fitted to quick detachable rims on the gasoline cabs. Standard rates are charged, and in addition to the regular business conducted from the private stands special services on a monthly payment basis and a regular flat rate service to and from Coney Island are conducted. The taximeters on the cabs of this company have always been driven from the front wheels. All repairs, including repairs to the taximeters, are made in the company's shops. A maintenance contract is in force with the tire manufacturers, but not with the car manufacturers. The average daily mileage of each cab is 25 miles. Drivers are paid regular wages on an hourly basis, with a higher rate for overtime. Gasoline and oil are furnished free. The amount of business varies greatly with the weather and other conditions, but usually the busiest hours are from 8 to 9 p. m. on week days and 2 to 4 p m. on Sundays.

THE NEW YORK TAXICAB COMPANY, with offices and garage at 622 West Fiftyseventh street, operates about 600 Darracq cabs, and states that this number is added to weekly. The weekly additions and the final number of cabs which it is intended to operate are, however, not given. The company also states that the cabs are operated from sixty stands, some of which are located as follows: Pennsylvania R. R. depot, foot of West Twenty-third street; Hotel Breslin, Imperial Hotel, Park Avenue Hotel, Marlboro Hotel, Victoria Hotel, Hotel Albany, Metropole Hotel, Manhattan Hotel, Rector's Restaurant, Churchill's Restaurant, Reisenweber's Hotel, Woodward Hotel, Wyoming Apartment House, Plaza Hotel, Netherland Hotel, Savoy Hotel, Marie Antoinette Hotel, St. Andrew's Ho-

tel. Majestic Hotel, Freundschaft Society. Central Park Casino, Bretton Hall, Harlem Casino, Colonial Hotel, St. Regis Hotel, Consolidated Stock Exchange Building, 26 Broadway, Madison Avenue Hotel, Flatiron Building, Strand Hotel, St. Denis Hotel, Lüchow's Restaurant, Hotel Chelsea, Mt. Sinai Hospital, Hotel Aberdeen, Martha Washington Hotel, 413 Broome street, northeast corner Broadway and Eightyeighth street, northwest corner Broadway and 100th street, northeast corner Broadway and 126th street, southeast corner Broadway and 145th street, and the Lafayette Baths. This concern has no maintenance contract with the manufacturers of cars and tires. Repairs are made in the company's shop. Drivers are paid a percentage of the earnings of their cabs. A regular flat rate service is conducted to Coney Island, the charge being \$5 for a cab for four persons from any point below Fifty-ninth street to Coney Island or re-

#### THE RENAULT TAXI SERVICE COMPANY.

with offices at 214 West Sixty-fifth street, operate fifty Renault cabs, and state that in the fall fifty additional cabs will be added to the service. A hacking business is conducted from six stands, the locations of which were not furnished by the management. Cabs are fitted with pneumatic tires and spare wheels, and the rates are as specified by the municipal ordinance. Taximeters are driven from the rear wheels, and all repairs are made in the company's shop. At present there is no maintenance contract in force with the manufacturers of the cars, but there is a contract with the tire manufacturers, the nature of which could not be ascertained. Fifty miles is stated to be the average daily mileage of each cab. Drivers are paid a regular salary, and gasoline and oil are furnished them free of charge. The company operate a few cabs on a regular monthly payment basis, and state that their cabs are busy about twelve hours each day.

THE UNION TAXICAB AUTO SERVICE COMPANY, with offices and garage at 230 West Fiftyeighth street, operate 17 Thomas, 4 Locomobile, 4 Stevens-Duryea and 11 Ewing cabs, and at an early date additional cabs will be added to the service. The business is conducted from six stands. The cabs are equipped with pneumatic tires, some of which are fitted to detachable rims, while the remainder have spare wheels. Taximeters are driven from the front or rear wheels. All repairs can be made in the company's shop. There is no maintenance contract in force with either the cab or tire manufacturers. The drivers are paid a regular salary, and are furnished with gasoline and oil free of charge.

THE UNIVERSAL TAXIMETER CAB COMPANY, with offices and garage at 153 East Fifty-third street, operate fifty Argyll cabs from stands at the Hotel Knickerbocker, the Astor House and Hotel Buckingham. This

number will be increased to 100 within a short time. The taximeters are driven from the front wheels. All repairs are made in the company's shop. Maintenance contracts are in force with the manufacturers of both the cabs and the tires. Fifty miles is given as the average daily distance of each cab. The operators are paid a regular salary and are furnished with gasoline and oil free of charge. The cabs are in greatest demand Saturday night from 8 p. m. until 2 a. m.

#### THE TAX-A-AUTOCAB COMPANY,

with offices and garage at 103 West 108th street, and formerly of 110th street and Eighth avenue, operate ten Thomas cabs, and in the fall will add as many cabs as the increase of the business demands. The company has a stand at Pahst's, 125th street. and a summer service is conducted from the new Monmouth Hotel, Spring Lake, N. J. Some of the cabs are fitted with solid tires, and the cabs having pneumatic tires are equipped with quick detachable rims or spare wheels. Heretofore the taximeters have been driven from either the front or rear wheels, but as early as possible the drive will be changed to the front wheels on all cabs. A maintenance contract is in force with the manufacturers of the cars, who will replace all parts proving defective in service, and a contract with the tire manufacturers is also in force. This company state that about 90 per cent. of the mechanical troubles with the cabs are traceable directly to the drivers. Seventy-five miles is given as the average daily distance traveled by each cab. The drivers are paid a salary and commission, oil and gasoline being furnished free of charge. On week days the busiest hours are in the early morning and in the early evening in summer, and in the evening in the winter. The amount of business done on Sunday depends to a great extent upon the weather. If the weather is pleasant many people take long trips, while if it is unpleasant short trips are made.

#### THE TAXI-SERVICE COMPANY,

with offices at 334 Fifth avenue and a garage at 142 East Thirty-first street, have fifty Berliet and fifty Sultan cabs in operation. This number is added to weekly. The business of the company is conducted entirely from stands, some of which are located as follows: Waldorf-Astoria, Holland House, Hotel Seville, Healy's Restaurant, Walcott Hotel, Park Avenue Hotel, Stratford Hotel, Colony Club, Belleclaire Hotel, Marseille Hotel, Leonora Hotel, Hermitage Hotel and the New Grand Hotel. All of the cabs are fitted with pneumatic tires, and at present the spare wheels in use are being superseded by quick detachable rims. Some of the cabs of this company are used as private vehicles on a monthly charge basis. The taximeters are driven from the front wheels of all cabs. All repairs are made in the company's shop. A maintenance contract on a mileage basis is in force with the tire manufacturers, but there is no such contract with the car manufacturers. The daily mileage of each cab is 50. The drivers are paid a regular salary and are furnished with gasoline and oil free of charge. The company, however, keeps a close record of the amount of each furnished to the individual cars, so that a monthly or weekly comparison can be made between the distance traveled by the cab and the amount of fuel and lubricant used. From 12:30 to 2 p. m. and from 7:30 to 8:30 p. m. are the busiest hours on week days, and from 12 to 6 p. m. on Sundays in summer.

#### THE TAX-A-CAB TRANSIT COMPANY.

with offices and garage at 55 West Ninetythird street, employ thirty-five cabs, some of which are electric vehicles fitted with solid tires. The gasoline cabs are of Atlas and Buick make. In the fall ten additional gasoline cabs will be put in service. The pneumatic tires in use on the gasoline cabs are fited with quick detachable rims. Special monthly or yearly private contract services are conducted, in addition to a regular hacking business. The taximeters are driven from the front wheels, and all repairs are made in the company's shop. The average daily distance traveled by each cab is given as 50 miles. The operators are paid a salary and commission, and are furnished with gasoline and oil free of charge.

#### THE WEST END MOTOR CAB COMPANY,

with offices at 1497 Broadway and garage at 246 West Fifty-sixth street, operate twenty-one Thomas cabs, and in the fall will increase this number to fifty. In addition to a regular hacking business the cabs are operated from stands at the Lotus Club and Engineers' Club. The cabs are fitted with pneumatic tires on quick detachable rims, and the taximeters are driven from the rear wheels.

All repairs are made in the company's shop, and 50 miles is given as the average daily distance traveled by each cab. The operators are paid a percentage of the earnings of their cab, and gasoline and oil are furnished to them free of chrge. The busiest hours on week days are from 7 to 9 p. m., and on Sundays from 2 to 5 p. m.

# THE WYCKOFF-CHURCH & PARTRIDGE TAXICAB COMPANY.

with offices and garage at 232 West Fiftysixth street, at present operate thirty-five Bristol cabs. This number is being added to at the rate of about five per week. The business will be conducted from stands located in various parts of the city. The cabs are fitted with pneumatic tires on quick detachable rims, and the taximeters are driven from the front wheels. Special services at monthly rates, as well as regular flat rate services to pleasure resorts, are conducted. All repairs are made in the company's shop, and there is a maintenance contract with the manufacturers of the cabs and of the tires. Forty-five miles is given as the average daily distance covered by each cab. The drivers are paid a regular salary. This service has been in operation only about three weeks.

#### THE WESTCOTT EXPRESS COMPANY

are operating a number of Berliet cabs from the Grand Central Station. These cabs are not fitted with taximeters, the rates being the same as for the horse drawn xehicles, in conjunction with which they are operated. These cabs are fitted with solid rubber tires, but the management having refused information relative to the operation of the service we are unable to state with what success. In Brooklyn regular taxicab services are conducted by two operating companies, in addition to about twenty-five privately owned vehicles fitted with taximeters.

#### THE GREEN TAXICAB COMPANY,

with offices and garage at 159 and 161 Clymer street, operate ten Autocar cabs from stands at the garage, and in summer from Steubenbord's Hotel, Coney Island, and regularly from Edgett's Café, the Borough Hall and the Hofbrau House. The cabs are fitted with pneumatic tires on quick detachable rims, and the taximeters are driven from the front wheels. A maintenance contract on a mileage basis is in force with the tire manufacturers. Fifty miles is given as the daily average distance traveled by each cab. The driver is paid a salary and commission, oil and gasoline being furnished free of charge. In summer the cabs are kept busy from 11 a. m. to 4 a. m. The service having been inaugurated only this season, the extent of the winter traffic is unknown.

# THE BROOKLYN TAXICAB COMPANY,

with offices at 100 Putnam avenue, operate twenty Thomas cabs, and in September will add twenty-five more. The cabs operate from stands located at 100 Putnam avenue. 8 Nevins street, the Clarendon Hotel and Silsbe's Restaurant. Pneumatic tires on quick detachable rims are fitted to all of the cabs. The taximeters are driven from the front wheels; all repairs are made in the company's shop. Fifty miles is given as the average daily distance traveled by each cab. the operators are paid a straight salary and are furnished with gasoline and oil free of charge. A special service at the following flat rates is conducted between Coney Island, Brooklyn and New York, the rates being the same for one to four persons: Conev Island to any Brooklyn subway station, or vice versa, \$3.50; to any point in Manhattan south of Fifty-ninth street, \$5; to any point in Manhattan north of Fiftyninth street and south of 100th street, \$5.50; to any point in Manhattan north of 100th street and south of 156th street, \$6.

Most of the above companies have their cabs painted in distinctive combinations of colors, and their operators are generally clad in uniforms of dark cloth with caps to match, and in some cases they wear leather leggings.

# International Standard Screw Threads.

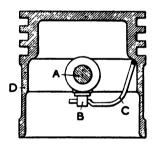

The following table of international standard screw threads may be of interest to those who have repair work to do on imported cars:

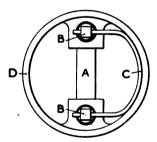

Angle of thread,	60 degree	es. Flat, 1/8	of P.
Diam-		Tap T	ap Drill,
eter.	Pitch.	Drill, Flat.	Sharp.
(Mm.)	(Mm.)	(Mm.)	(Mm.)
6	1.00	5.2	5.
7	1.00	6.2	6.
8	1.25	6.8	6.5
9	1.25	7.8	7.6
10	1.5	8.5	8.3
11	1.5	9 · 5	9.3
12	1.75	10.2	10.
14	2.00	11.8	11.5
16	2.00	14.	13.8
18	2.5	15.2	15.
20	2.5	17.2	17.
22	2.5	19.2	19.
24	3.00	20.6	20.5
27	3.00	24.	23.8
30	3 · 5	26.	25.8
33	3 · 5	29.	28. <b>8</b>
36	4.00	31.5	31.3
39	4.00	34.5	34.3
42	4.5	37 •	36.8

Pitches of sizes between standard diameter are the same as for the next smaller standard diameter.

# Novel Method of Securing Wrist Pin Set Screw.

The sketch herewith, taken from our French contemporary Omnia, shows an unusually secure method of holding the pis-

METHOD OF SECURING PISTON PIN.

ton pin in place in a vehicle motor. The pin itself is held by two square headed set screws. The heads of the set screws are drilled through. A length of steel spring wire is bent to such shape that its central portion will rest against the shoulder in the wall of the piston when the two ends are slipped through the holes in the screw heads. The ends of the spring are offset so as to limit the distance the ends pass through the heads of the set screws.

# Running Schedule and Diagram Chart Showing Details Pertaining to the Operation of a Taxicab Service.

BY EDWARD WELLS.

The accompanying chart and diagram have been designed to fulfill the following purposes: To supply the directors and management with a comprehensive sheet covering the actual car operations of the entire equipment for stated periods, which will include all important figures and data relating directly thereto, compiled in a simple and discernible manner; a sheet which will enable the management to determine upon the various "shifts" for all cars for a given period in advance, and which will also enable them to follow the various movements of these cars daily and without the necessity of going through detailed reports in order to obtain the information they may seek. One of the principal purposes is to enable them to follow the movements of any car, to compare its earnings and expense of operation with those of any other car or cars, so that if at any time certain cars fail to show the average earnings, this fact may be readily discovered and the cause ascertained and remedied, without the liability of such facts continuing long unnoticed, as would be the case where individual reports only are made, rendering it necessary to go through each one in turn. It is also easy to observe the fact of any car or cars being laid up for repairs, as these are shown by red dashes on the diagram covering the period during which the cars are out of service because of this necessity. In the event of more details concerning any individual case of repairs being required, the repair department ticket for the car in question may be obtained from the superintendent.

Care has been taken to show upon this diagram only figures relating to the actual operation of cars, and it has not been considered necessary to include the apportionment of various overhead and indirect charges, which will, however, be done upon the regular monthly statistical reports of the company. Therefore, under the heading "Operative Expense of Each Car" have been included the following items only: Chauffeurs' wages, proportionate wages of starters, wages of cleaners, actual cost of repairs (including cost of labor, but not supervision), cost of gasoline, oil and waste used, and mileage cost of tires. In order to determine the net profit, it will be necessary to add to the foregoing a proportionate amount on the following indirect expense and charges: Garage rent, salaries of superintendent and minor garage officials, salaries of officers and office employees, office rental, advertising, insurance, incidentals and depreciation of rolling stock.

As previously stated, all of the foregoing will be taken into account upon the regular monthly or periodical reports, as will also more detailed information concerning the

actual number of passengers carried and recapitulation of various other items.

AN EXAMPLE

To enable one to more readily understand the accompanying sheet and its actual use, a few examples will be given herein.

First, we find that the running schedule for all cars is laid out in advance by a system of dashes, which indicate the hour upon which each car is dispatched upon its run daily, as well as the hour of its return to the garage. In the event of the car coming in disabled before completing its regular run, a red dash is made (this is figured to the nearest quarter day), and this dash is continued along the other line while the car is laid up. Thus upon reference we find that car No. 3 with regular driver No. 103 in the first division, under Foreman John Smith, was dispatched upon its regular shift on Tuesday, October 13, at 7 a. m., but returned disabled at 7 p. m., six hours before the close of the allotted day's run for this car, and that it remained in the repair shop for 18 hours (running time) or 36 hours (actual time) going on again Thursday, the 15th, at 7 a. m., remaining upon its regular schedule up to Tuesday, the 20th, when it again reported in for repairs at 7 p. m., which repairs were made in time to enable the driver to take it out as usual the following day. We find, therefore, in the case of the foregoing, that out of the scheduled 210 running hours for the period of 14 days, this car was in actual service 186 hours, having been in the repair shop during 24 of its scheduled running hours.

The movements of every car in the service may be similarly determined by glancing at this diagram. For instance, we find that car No. 9 under regular driver No. 109 remained in service during the entire period shown, without reporting in for repairs at any time. The comparative gross receipts and net earnings of each car are readily ascertained by glancing at the columns under these respective headings. For instance, we find that the gross receipts of car No. 6 for the 14 days were \$371.10, and that the operative expense for this car was \$121, indicating a net earning of \$149.90.

We also find that the total mileage run by the car just referred to was 960 during this period, of which 760 miles is designated as earning mileage, the remaining 200 miles being "deadhead mileage" (so called).

We are also able to determine just how many cars are in service during each shift every day. For instance, we find that upon Friday, the 16th, from 7 p. m. to 1 a. m., there were 14 cars in service. There should be 15 upon this shift regularly, but in this instance car No. 8 was in the repair shop at the time stated.

Substitute drivers are shown by a blue

X and are designated individually by letters, A, B, C, etc. Upon this diagram arrangements are made in advance to allow each regular driver to be off duty one day out of seven, at which time a substitute will take his car. In the event of regular drivers being off duty unexpectedly, a substitute will, of course, take their place, and this will also be shown upon the diagram by a blue X. As an example of following the movements of the substitute drivers, we find that driver B takes car No. 3 on Monday, the 12th, at 1 p. m.; that on Tuesday, the 13th, he takes car No. 5 at 1 p. m., etc.

The various figures shown upon this diagram are entered from day to day or at stated periods from the daily or periodical reports, which will be furnished by the operative department.

All figures and statistics will be so counterchecked and proven as to render it impossible for any employee to furnish fictitious reports without detection.

In addition to giving information concerning each car for a stated period, this diagram also gives certain detailed information concerning all cars daily. For instance, under date of Saturday, the 17th, we find that there were in the repair shop cars the time for repairing of which aggregates twenty-four hours, whereas under date of Tuesday, the 13th, the aggregate hours for repairing amount to but six.

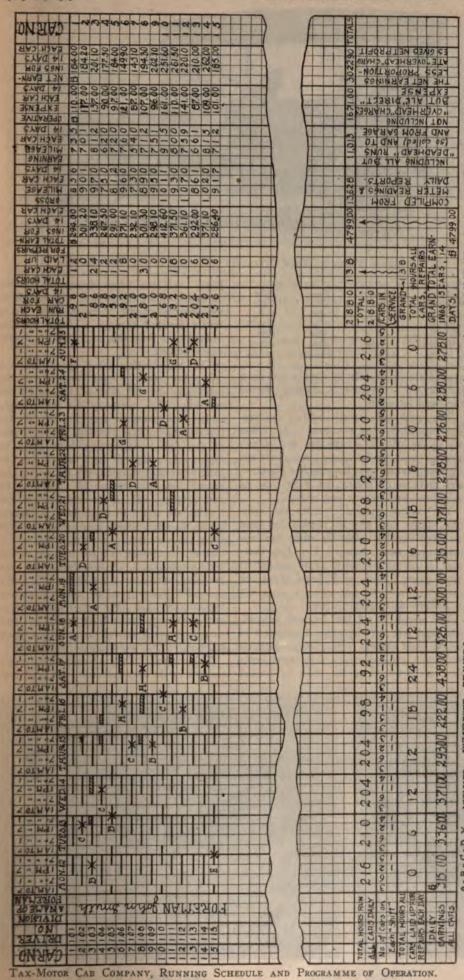

It may prove very expedient to have this to refer to in the case of there being claims of congestion in the repair department from time to time, it being easy to make comparisons of the figures given in this manner. We also have the gross receipts compiled daily, as well as the gross mileage run by all cars, and the total hours in service daily for all cars.

It will be seen that provision has been made to have all cars in service during the busiest hours of the day, i. e., from 7 p. m. until I a. m., and that certain cars remain in service during the entire night; also that there are more cars in service during the afternoon hours than during the forenoon. The number of cars on each "shift" may be varied to suit the actual demands upon the service.

In the accompanying chart and diagram various figures and dates are used for example only, and have no bearing upon the actual prospects of operation of the company.

While the movements of only 15 cars are shown, the same system can easily be used for any number up to 150, without confusion. In case more cars than these are in service, it will be advisable to utilize more than one sheet at a time.

[As the diagram originally furnished by the author is in colors, it is not possible to exactly reproduce it in the paper, but a word of explanation will make clear the differences between the original and the reproduction. The cross sectioned rectangular spaces in the diagram, which indicate periods of time the cars are in the repair shop, are red pencil lines in

the original diagram. The marks Ax, Bx, etc., which indicate that the car was being driven by a substitute driver, are in blue pencil in the original diagram. The horizontal line showing the "Total Hours All Cars Laid Up for Repairs Each Day," and the vertical column, headed "Total Hours Each Car Laid Up for Repairs," are in red ink. The horizontal line showing "Daily Earnings All Cars," and the vertical column showing "Total Earnings for Fourteen Days Each Car," are in yellow ink. The two columns headed, respectively, "Operative Expense Each Car Fourteen Days," and "Net Earnings Each Car for Fourteen Days," are also in yellow ink .- ED.]

# Conditions Tending to Quiet Running of Motors.

The Association of Licensed Automobile Manufacturers is sending out a circular in which the conditions tending to quiet running of gasoline motors are discussed. Some of the principal causes of timing gear noises are inaccurate machine work in the crank case, leading to too wide variations in the distance between gear centres; unsuitable crank shaft and cam shaft bearings, causing jumping of the shafts when the motor is running; inaccurately spaced and poorly designed gears, causing warping after the strain of cutting the teeth is removed. The utmost care must be taken in fitting up cam gears.

The chief cause of the noisy operation of timing gears is the intermittent load due to the lifting action of the cams, causing intermittent pressure on the teeth, and even reverse pressure, producing slapping of the gear teeth due to backlash. In order to reduce this cause of noise to a minimum the weight of the valve mechanism should be made as small as possible, the valve springs made as light as possible, relatively non-resonant material should be used; the cam should be shaped to give a gradual action to the valve plungers, and the gears should be made with a proper pitch and effectively lubricated.

The noises from pistons, connecting rods and crank shafts have been practically eliminated by accurate machine work, level bearing surfaces and proper Inbrication methods. Pistons and connecting rods must be made as light as possible, and all in the same engine of equal weight. The crank shaft must not be made too light, and undue sideplay of the connecting rods must be avoided. The main cause of valve noise is the slapping of the valve on its seat. The valve's descent should be gradually arrested just before it strikes its seat by a very gradual taper of the cam incline. The valve springs should be of sufficient strength to keep the roller in contact with the cam. One experimenter claims that if the cams are properly designed the seating of the valves cannot be heard outside the motor, with the manifolds, carburetor and muffler connected.

# NEW VEHICLES

## Peerless 1910 Models.

The Peerless line for 1910 will consist of three distinct chassis models, viz., a four cylinder 20 horse power, a four cylinder 30 horse power, and a six cylinder 50 horse power. The latter two will be made in different lengths of frame, for roadster and touring bodies respectively, so in one respect five different models will be turned out. A wide variety of body types is offered the purchaser. The following table gives the main dimensions of the five models.

The 30 horse power and 50 horse power

PERLESS MODEL 27. FOUR CYLINDER, 30 HORSE POWER TOURING CAR.

Model.	Rated H. P.	Cylinder Dimensions.	Wheel Base.	Front Tires.	Rear Tires.
27 Roadster		476×51/2 476×51/2	11836	36x4	36x5
28	. 50	476×51/6	136	36x4	36x5
28 Roadster		476×536 4 ×436	13252	36x4 32x31/2	36x336

models are developments of last year's car, but the 20 horse power is a new design of the town car.

The new models present no radical changes in appearance. The radiator and bonnet are precisely the same, and the body is of the same dimensions. Between the front seat and dash the toepiece is carried up to the dash in a curved line instead of at an angle as heretofore, and the medallions which have heretofore been used in the moldings are now eliminated, the moldings being straight, which is desirable in order to get the best striping effect.

The construction of the motor is essentially similar to 1909 models. The oiler, however, is of new design, and all the pump mechanism is now placed in the oil reservoir, which is, as formerly, a part of the aluminum crank case. The oil level in crank case is regulated by standpipes as formerly, but the pet cocks attached thereto may be

opened simultaneously by simply turning a thumbscrew conveniently located behind the hand oil pump.

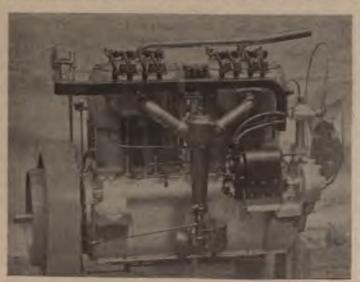

The spark and throttle control mechanisms are somewhat improved. All joints are of the ball and socket type and adjustable for wear, so that these connections are extremely sensitive to the operator's control, and there is no chance for such wear as will cause backlash or lost motion.

The cooling system includes the same type, shape and size of radiator as used in 1909, together with the same herring-bone gear water pump. The fan, however, is driven by spiral gears instead of bevel gears. Such small bevel gears are extremely hard to cut, and are more apt to become noisy through use.

The clutch is of the internal expanding band type, of the same dimensions as in the 1908 model. The pedals operating the clutch and brake are of different type; they are attached to the shaft by hinged joints and thus adapt themselves to the normal position of the foot, which adds to the security of the operator. The shafts thrust forward through a small opening instead of a long slot, as in 1909 and previous models.

The transmission (four speed selective type) has been brought forward on the sub-frame for the sake of convenient inspection. By removing the floor board under the operator's feet, the top of the transmission case is exposed. In the cover of the case is fastened a hand plate by means of a bayonet lock, which can be instantly removed to expose the gears and provide an easy means of supplying oil and grease. All of the mechanism for locking the gears in mesh is now housed inside the transmission case proper, so that there are no exposed working parts to exude oil, accumulate dirt and present an unsightly appearance. A new device has been provided which is claimed to effectually prevent leakage of oil or grease from the transmission case. The speed change lever and emergency brake lever have also been carried forward and set in a more vertical position, so they are more easily reached.

This change in the transmission is important in the respects mentioned, and also

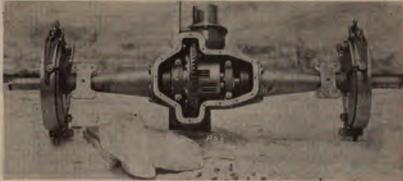

EXHAUST SIDE.

MODEL 27 MOTOR,

INLET SIDE

REAR AXLE AND CHANGE GEAR.

because of the decrease in the angularity of the propeller shaft; that is to say, the universal joint connections between the transmission and rear axle are more nearly in a straight line, and, therefore, loss of power and wear on these parts will be reduced.

In the propeller shaft the same kind of universal connections are provided for either end as in 1909 models, except that the housing is materially improved. There is a metal housing on each end of the universal joints, and between these housings there is provided a telescoping leather shield. These parts are very accessible,

Instead of the tubular type torque rod used in 1909 models, a pressed channel steel rod is now used, which is a little lighter and somewhat stronger, and, furthermore, in this type of construction there is no brazing, which it is always desirable to avoid where practicable.

As in the past, the front axle will be of I-beam construction, but will be of imported forgings.

The springs have been lengthened, the front 2 inches, and the rear 4 inches. They are imported from Lemoine, France, and are made from silico-manganese steel.

Each model of car will have two absolutely independent ignition systems.

A high tension magneto will be provided, and besides the same battery, spark coil and commutator system as used in 1909 will be carried. Two sets of plugs are used, and each connects separately with its own spark generating system, so that each may be used entirely independent of the other. The four speed selective type transmission is continued in practically the same form as in 1909. Platform spring suspension will be used in the 1910 models.

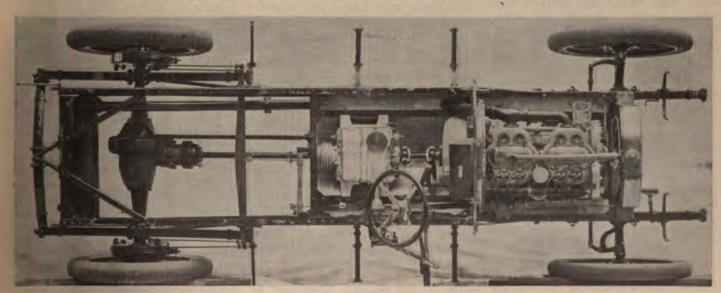

The new town car will be fitted with either landaulet or limousine bodies. Its design in general follows that of the larger cars, comprising such features as the four speed selective transmission, platform spring suspension, etc. But a departure has been made in placing the driver's seat at the left, with the gear shifting and emergency brake levers in the middle. It is claimed that this arrangement is very desirable for a car to be used chiefly in city traffic.

## The Multi Unit Motor.

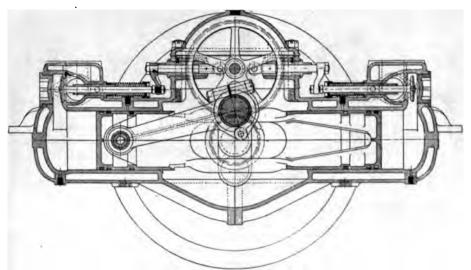

A novel type of four cylinder vehicle motor has been placed upon the market by the Multi Unit Gas Engine Company, of Chicago. The motor is of the four cycle, horizontal type. Among its chief features is the double headed piston construction, which is patented. Only two piston castings are required for the four cylinders, each of these double pistons acting on one connecting rod, whereby the throws of the crank shaft are reduced from four to two, and two connecting rods with their bearings are eliminated. The crank shaft is necessarily much shorter and more rigid than a four cylinder crank shaft of conventional design. The general design of the motor is claimed to lend itself to simplicity, accessibility and compactness.

The cylinders are cast in pairs, with onehalf of the crank case cast integral with each pair. Thus, the four cylinder motor comprises only two castings, which are joined in the centre plane of the motor. The three crank shaft bearings are located between the two castings. As the valves are located in chambers on the upper side of the cylinders, the cam shaft is placed above the crank shaft in a removable frame, which is enclosed by a cover, and all working parts are protected from dust, etc. The motor is operated on moderate compression and is provided with a flywheel of generous diameter and weight. The use of large valves and a large flywheel is said to allow of throttling the speed down to as low as 60 r. p. m., and, on the other hand, to run it up as high as 2,200 r. p. m. All the castings are produced in the foundry of the manufacturer.

The cylinders are first rough bored and are then heat treated and "aged" to relieve

PLAN OF CHASSIS.

MULTI UNIT VEHICLE MOTOR.

all strains, after which they are finished by grinding. The pistons, which are cast in pairs, are also heat treated, after which they are ground to a perfect fit. The ring grooves are cut with a special tool to insure the greatest degree of gas tightness. The piston pin is secured in the piston by a positive locking detent or dog.

The connecting rods are made of vanadium steel and are provided with a hinge joint at the crank end, and with shims to facilitate the taking up of wear. The crank shaft is made from a drop forging which has the flange to which the flywheel is secured forged integral with it. The crank pins and main bearings are said to be of larger diameter than ordinarily used, and all bearings surfaces are ground. The bearing journals are drilled for oil. The bearings are lined with Parsons white bronze, the bushings being die cast and interchangeable. The outer bearings are provided with oil-retaining grooves and felt dust washers.

The valves are of the combination nickel steel head, carbon steel stem type. They have 45° seats and are interchangeable, all valves being mechanically operated. The cams are integral with the cam shafts, which latter are hardened and ground and are driven through bronze and steel gears. The push rods are of steel, hardened and ground, and provided with hardened steel adjusting screws. A shaft for the timer extends vertically at the side of the motor, and is carried in ball bearings and driven by a pair of enclosed bevel gears. An oil pump is provided in the crank case which keeps the oil in the crank case for splash lubrication at a constant level. Oil ducts are cast integral with the cylinders, and regulating check valves are provided so that the oil feed to the cylinders may be adjusted at will. The manufacturers claim that the motor is economical in the use of both fuel and lubricating oil.

The Woodhull Carriage Company, of Dayton, Ohio, is considering the manufacture of automobiles.

# A New Heinze Magneto.

The Heinze Electric Company, Lowell, Mass., has just brought out a high tension magneto which embodies some decidedly interesting features. The accompanying illustration gives a good idea of the external appearance of this magneto, which is of the low tension armature type, with step-up coil. dashboard mounted.

Special attention is paid to the field construction in view of the following considerations: The voltage generated by any magneto is proportional to the product of the total magnetic flux which is reversed through the armature core, the angular speed of the armature and the number of conductors thereon. Magnetos are now required to generate a useful sparking voltage at a very low angular velocity, so that they may start the engine when it is cranked and fire the charges positively at very low idling speeds. The speed factor in the voltage formula must thus be kept very low. The number of armature conductors must be kept low for various reasons. If a large winding space be provided, it is at the sacrifice of the iron cross section in the armature core, which leads to high magnetic reluctance therein, excessive leakage, and a diminution of the effective flux to be cut by the windings.

As a result of these considerations the closest attention must be paid to increasing the available field strength. This may be accomplished by the use of a large number of large field magnets, but this is commercially out of the question, as the bulk and weight of the magnets must be kept down within reasonable bounds. The desired result may also be accomplished by the use of magnets of reasonable size and weight, if the reluctance of the magnetic circuit be kept low and the leakage factor be minimized.

It is along this line that the Heinze magneto has been designed. It has been realized that a large proportion of the total reluctance of the magnetic circuit resides in the magnetic joints and in the air gap, and that very large contact

areas, close fits, and large flux areas are essential. Since the reluctance of two given magnetic joints, equally perfect mechanically, is inversely as the contact areas, very liberal contact surfaces are provided, and, since the reluctance of an air gap is also inversely proportionate to its flux surfaces, liberal polar areas are provided.

Instead of using magnets of conventional, flat, rectangular cross section, magnets of circular cross section are here employed, for several reasons: Steel of this section is less liable to crack in the hardening process, magnetic leakage is reduced, as there are no corners or portions of high radius of curvature, and, further, an improved method of jointing to the pole pieces is made possible.

Four U-shaped magnets of circular section furnish the field, and the ends of each magnet are ground to a uniform taper. This taper exactly coincides with the form which is given the holes in the pole pieces, which are to receive the magnet ends-a special reamer being employed. The magnet ends are forced into these holes under pressure and it is to be noted that the whole perimeter of the magnet end is in magnetic contact with the pole piece. This is not the case when rectangular magnets, having one side only pressed against the pole piece by the tension of one or two small machine screws, are used. In the case of fields having superposed magnets of rectangular section, the contact of the outer magnet with the pole piece is even less intimate, as the flux which it creates has two air gaps to overcome before reaching the pole piece.

Pole pieces of cast iron are used and the polar arc is large. The armature core is of somewhat unusual construction and material. Cast iron is employed, the usual laminated construction being discarded. Repeated tests have demonstrated to the satisfaction of the Heinze Company that the solid armature gives better results than one built up from stampings. While the cross section of the armature is roughly of shuttle shape, the slots are very much shallower than usual, leaving the main body of the shuttle of very much larger section. The horns of the ends are not as abrupt as usual, but are much more "stocky." The effect of this design is to reduce the reluctance of the armature core, which runs between the pole pieces, with a minimum clearance. Furthermore, the shape of the armature horns is such that the lines which pass through the iron always have a straight path, and are not abruptly bent. To this point of design is attributed the fact, which can easily be demonstrated by trial, that there is little variation of torque observable in turning the armature over. The shallowness of the wire slots is understood to be more than compensated for by the resulting low reluctance of th earmature core. Although but a fraction of the usual number of armature turns are employed, it appears that the increased activity per turn, due to the larger number of lines cut, more

than makes up for the reduced number of conductors.

So high is the conductivity of the magnetic circuit that it is the practice of this company to work their magnets at a somewhat lower degree of saturation than that ordinarily used. It is a well known fact that the lower the flux density the greater the permanence, other things being equal. The claim is made that the magnets used will not deteriorate more than 5 per cent. in 50,000 miles of running.

Magnetic leakage from the pole pieces is minimized by carefully rounding all corners. The armature shaft, with its cam, is carried upon annular bearings, and its driven end is furnished with a pin which works in the helicoidal slot of the driven sleeve which carries the universal joint. The advance and retard are obtained by a bell crank lever which moves the sleeve relative to the shaft, and thus changes the angular position of the armature shaft with relation to the magneto shaft of the engine. The regularity of the magneto torque referred to above allows this to be done without wear or strain upon the shifting mechanism. A total advance of 90 degrees is provided, but the break of the primary circuit is always at the peak of the voltage curve, which oscillograph determinations show to be very abrupt. By thus producing the spark at the maximum point low idling speeds of the engine can be taken care of. The make and break mechanism is of the roller actuated type, with all parts hardened, and the contacts are of platinum-iridium, and very liberal in size.

A round, radial gauze brush serves to collect the armature current, and a similar brush bears upon the shaft and positively grounds it. The make and break box is fixed in position, but may instantly be detached by the removal of two screws. It and all other parts are waterproof. The two primary cables coming to the break box are permanently fixed to their substantial contacts by soldering, and will be made of

any specified lengths. This does away with binding posts.

Just above the armature is located the condenser. It is of the "rolled up type," of mica and tinfoil, and is housed in a watertight removable brass casing. Its location at the magneto considerably simplifies the wiring required.

The following figures are given out as to the performance of this magneto: At 1,000 r. p. m. the primary voltage is 6.8 and its short circuit current amounts to 5.7 amperes; at 50 r. p. m. the magneto will produce a spark three-eighths of an inch in length.

The distributor gears are housed in a steel casing, and the distributor shaft is on annular ball bearings. For the distributor itself a sort of unit construction is employed, the distributor sections, in the form of triangular vulcanite units, being grouped in line on the shaft. The number of sections used corresponds with the number of engine cylinders. Each section carries a contact molded into its upper internal surface, to which its appropriate cable is permanently attached, the cable length being made as specified. All cables leave the distributor from the top. and if the order of cylinder firing is specified they can be so arranged that there need be no crossing of cables.

For each distributor section the distributor shaft bears a contact arm which travels in close proximity with, but does not touch, its corresponding fixed contact. The production of metal dust, with its liability of short circuiting, is thus avoided. The conformation of the distributor sections, which are of a special heat resisting, vulcanized rubber, is such that there is no possibility of a discharge from one to another, with its liability of producing a back fire. Connection from the high tension side of the dashboard coil to the insulated distributor shaft is by a heavy cable and a substantial contact. The distributor is readily accessible, and the construction is such that by changing the angular relation of the moving contacts upon the shaft any order of firing and any desired spacing may be attained.

The step-up coil used with this magneto is of standard Heinze construction, save that it has two primaries of appropriate winding for the magneto and for battery current, respectively. In the battery primary is included a regular Heinze vibrator. When the switch, which is of standard Heinze type, is thrown on "battery," the vibrator acts and the secondary current is distributed by the magneto distributor for starting purposes. When the switch is thrown to the "magneto" position, the battery circuit is interrupted and the magneto primary circuit made.

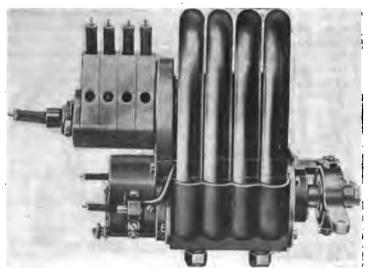

These magnetos are made with bases to fit any engine bracket and for motors of any number of cylinders, both four and two cycle. The weight of the machine is given as 20 pounds.

## New McCue Floating Axle.

The McCue Company, of Hartford. Conn., have made a number of changes in their floating type of rear axle for the 1910 season. A line cut of the new design is shown herewith. It will be seen that the axle comprises a steel housing which is welded laterally, with openings in front and back. The front opening is covered by a steel dome which is integral with the torsion tube extending forward to a bracket attached to a cross member of the frame. the same as on the latest style Fiat axles. Fitted into this dome is the differential gear case, which is supported by the rear cover, which is bolted to the axle housing. All revolving parts are carried on annular ball bearings, and self seating thrust bearings of ample dimensions are provided to take up the end thrusts. The rear axle driving shafts are made of .45 carbon steel, heat treated, with the hub clutches forged integral, not welded. The hub flange and the bearing surface of the large drum are

Heinze Low Tension Magneto.

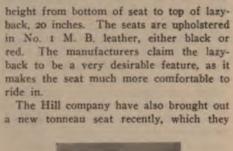

accurately machined, making it possible to assemble the wheels so as to run perfectly true. The hubs are provided with two brake drums of 10 and 14 inches diameter respectively. Both sets of brakes are of the expanding type, being operated by cam shafts

extending under the frame and connecting in a direct line with the equalizer bars. The brakes can be adjusted by means of the small cam shafts at the rear of the axle, which make a very simple adjusting means. The spring seats are made either to key on to the axle or to swivel, as desired. The axle shown in the illustration is designed for cars weighing 2,500 pounds or less. For heavier cars another

axle of the same type is being brought out which comprises a larger housing, larger gears and a larger size of bearings.

# Hill Folding Back Rumble Seat and New Tonneau Seat.

A rumble seat with a folding lazyback, as shown in the accompanying cut, is manufactured by the Hill Manufacturing Com-

Lazyback folded.

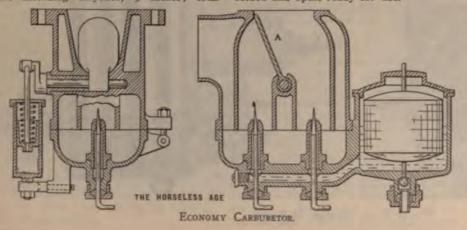

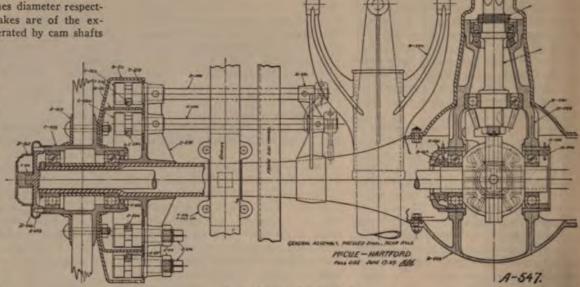

Open.

HILL RUMBLE SEAT.

pany, 25-27 Fuller street, Buffalo, N. Y. The seat has a spring cushion and is of the following dimensions; Width, 17 inches; depth, 16 inches; height of back of seat, not including lazyback, 9 inches; total

refer to as their No. 15 seat. This seat folds up more compactly than their No. 18 seat, and also sells at a lower price. The accompanying cut shows the seat both folded and open, ready for use.

NEW McCue Rear AxLE.

The seat is fastened to the side of the body on top of the sill. The socket has a 3% inch square hole through it, tapering to 5% inch at the bottom, thus insuring a good fit. The cushion is round and 13 inches in diameter, and the back is 17 inches

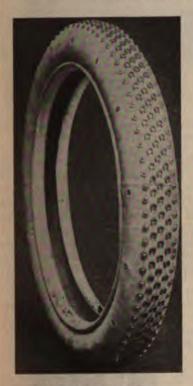

HILL TONNEAU SEAT, high. The seat has spring cushions and is trimmed in No. 1 M. B. leather.

# The Economy Carburetor.

Albert T. Otto, of 1876 Broadway, New York city, the American sales agent for Saurer commercial vehicles, has recently placed the Economy carburetor on the market. This carburetor is covered by patents owned by the Saurer company, and is used in the Saurer commercial vehicles, which made such a good showing in the recent competition held by the German Imperial Automobile Club. This carburetor has two nozzles, one of which works continuously, the other coming into action when the depression in the inlet pipe is sufficient to lift the clack valve A off its seat. This valve is retained on its seat by an adjustable coiled spring, which is enclosed by a dash-post, in which a plunger slides to prevent the valve from opening and closing too quickly. Each nozzle is provided with a needle valve adjustment, and all of the air taken in by the engine must go past the nozzles, there being no auxiliary air passages.

The "Horse Shoe" Tire.

he Beebe-Elliott Company, of Racine ction, Wis., are marketing a new ther pneumatic tire with a special m of renewable rivet washer. The conaction is plainly shown in the accomying photograph. The tread of the tire provided with two outer rows of plain flat headed steel rivets, and with middle s of rivets with "horse shoe" washers. e greater part of the road wear, of rse, comes on these middle rows. The se shoe shaped washers are originally de in the form of a U, which permits slipping them under the regular rivet ds. The washers are then closed by ding the ends together, and then form up into which the road dirt packs hard country roads. It is claimed that the t which fills these cups takes much of the ar from the metal, and that the combi-

THE HORSE SHOE TIRE.

tion gives much longer service than the dinary stud. When the cups become too ich worn to hold dirt, and when the et heads within them begin to wear, the els of the horse shoes may be spread and horse shoes taken out and new ones t in their place. It is stated that this ocess of renewing the washers can be acimplished at the rate of one per minute. special tool to open and close the washer furnished with the tire.

New Light Motor.

The Requa-Coles Company, of 206 oadway, New York city, are developing new light weight high speed internal comstion engine suitable for automobiles and ronautic use. The motor operates on the ur cycle principle, and because of a scanging puff of pure air introduced at the d of the exhaust stroke the motor is said to be much more flexible and more powerful than the conventional type of four cycle engine. Hugo C. Gibson is acting as consulting engineer for the company.

# Hupmobile Factory Nearing Completion.

The Hupp Motor Car Company, of Detroit, is completing the removal of its equipment and the instalment of new machinery in its new factory at Concord street and Jefferson avenue. The site of the new building adjoins the first automobile plant built and operated in Detroit-the former Olds works. With the exception of the part facing Jefferson avenue, where the office will be housed, the building will be one story high, and all the work will be done on the same level. The building has the shape of a huge capital U, each of the wings being 350 feet long and 50 feet wide, with the connecting portion 131 feet long and 60 feet wide. The building of cars will begin at one extreme end and the work will progress through the building until the cars are completed and ready for shipment at the other end. The capacity of the new factory will be 25 completed cars a day. Of the men connected with the company, R. C. Hupp, C. D. Hastings, E. A. Nelson, C. H. Dunlap and J. H. Peterson, are all former Olds men, and all entered the industry when the Olds factory was located on Jefferson avenue. J. Walter Drake, a Detroit attorney, is president of the Hupp Company.

New Wisconsin Auto Manufactur-

ing Company.
The Badger Automobile Company, of Columbus, recently organized with \$50,000 paid-up capital, and \$100,000 capital stock, has elected the following officers: President, A. M. Bellack; vice president, C. Kurth; secretary, George Holtz; treasurer, J. R. Wheeler; directors, Messrs, Bellack, Kurth; Holtz and William C. Leitsch. M. R. Arbogast, designer of the "Badger" car, which will be manufactured by the company, has been elected general manager of the company. C. Kurth is president of the Kurth brewing interests. General Manager Arbogast has returned from the East, where he purchased such parts as will not be manufactured by the company. The company plans to manufacture 250 cars for 1910 delivery.

New Factory for Edmunds & Jones.

The Edmunds & Jones Manufacturing Company, lamp makers, of Detroit, have found it necessary to provide larger manufacturing facilities, and about the first of September will move into a new factory located at 432 to 456 Lawton avenue. The factory building will be of brick and concrete, 60x215 feet, three stories high. In addition there will be a modern power plant, 40x58 feet. The new location provides shipping facilities over the Lake Shore, Michigan Central and Grank Trunk railroads. Ample land for further additions has been secured. Present plans include the manufacture of a full line of oil, acetylene and electric auto lamps, and an increasing production of marine lamps.

New Body Factory in Detroit.

The Griswold Motor and Body Com-pany has recently begun business in Detroit, Mich., in a factory building at Com monwealth avenue and the railroad, which is 90x110 feet in dimensions. The officers of the company are: H. F. Marsh, president; M. Griswold, vice president; A. F. Marsh, treasurer; Louis Smith, secretary and general manager, and Elmer E. Day. superintendent. The company starts with twenty-five hands, but plans to immediately start work on a 42x85 foot addition, and to greatly increase its force before winter.

Cole Motor Car Company Sales

Arrangement.
The Cole Motor Car Company, recently organized to take over the automobile manufacturing business of the Cole Carriage Company, Indianapolis, states that the entire output will be handled by the Henderson Motor Sales Company. Those interested in the sales company are J. J. Cole, Indianapolis; Charles P. Henderson, formerly with the Henderson-Hull Company, Savannah, Ga.; H. C. Lathrop, until recently manager of the Indiana branch of the A. D. Baker Company; Dr. A. B. Lathrop, of Swanton, O., and Leonard Carter, of Jessup, Ga.

Schweppe & Wilt Incorporated. The firm of Schweppe & Wilt, corner of Meldrum and Champlain strets, Detroit, Mich., has been incorporated as the Schweppe & Wilt Manufacturing Company, with a capital stock of \$70,000 and the following officers: President, W. H. Schweppe; vice president and general manager, A. D. Wilt, Jr.; secretary and treasurer, Marvine Gorham. The company has purchased considerable machinery from the old Pope-Toledo plant. The firm manufactures a line of automobile parts.

Tire Prices Rise.

A circular sent last week to automobile manufacturers all over the country announced an advance in the price of tires of from 15 to 25 per cent. The tire manufacturers' branch of the Motor and Accessories Manufacturers recently held a number of meetings in Cleveland and Akron, Ohio, at which the subject was discussed, and an increase in prices was decided upon to take effect on July 9.

The Aero Club of Michigan.

Under the above name a society has just been organized in Detroit for the encouragement of all branches of aeronautics. William E. Metzger is the temporary president, and many other local automobile men are among the charter members. The list includes such well known names as B. F. Everitt, H. E. Coffin and C. F. Splitdorf.

# Electric Lamps for Automobiles.

By MARTIN P. RICE.

Electric lamps have two important advantages for automobile lights which ought to insure their universal adoption. The first is safety and the second is convenience. The increased speed of gasoline driven vehicles under conditions and upon roads designed for horse traffic involves a sufficient element of danger without introducing the risk of fire from oil or gas lamps. While not, perhaps, so vitally important as safety, convenience is an advantage not less appreciated by all users of automobiles. Stopping to light up is sometimes annoying, particularly on a windy night, and the regulation of generators, gas tanks or oil wicks is usually more or less of a nuisance.

All this is avoided by using electric lamps. They eliminate flame and inflammable material. They are lighted and extinguished instantly by a switch within easy reach of the driver. For cleanliness they are unsurpassed. They produce no soot or smell, and there is no oil to leak or collect dust. There is practically no heat, so that the silvered mirrors cannot be damaged. The interior surfaces of lanterns fitted with electric lamps stay bright and clean. The electric system involves no difficulty in summer or winter; in fact, it is ideal for automobiles.

#### LAMPS.

The success of the system depends, however, upon the selection of suitable lamps and batteries, and upon their proper installation. Carbon filament lamps, because of their low efficiency, would require a battery of almost prohibitive size and weight, but tungsten lamps can be operated from batteries of reasonable weight and dimensions.

The filaments of these lamps for low voltages are short and strong enough to resist the jar and vibration incident to automobile service. No special spring support is necessary, and regular sockets can be used. Usually 6 volt lamps are employed, because this is the common voltage of ignition batteries, but 8 volt or 4 volt lamps may be used if preferred. The following equipment of tungsten lamps has

been found suitable for a touring car or runabout designed for town and country use: Headlights, two 10 to 20 candle power; side lights, two 2 or 4 candle power; tail light, one 2 candle power.

The filaments of headlights must be of compact form, so that the light is concentrated practically at a point which may be adjusted to the focus of the mirrors. If the filament is not compact, light is wasted by scattering. Several leading manufacturers of automobile lamps are now making brass lamps with reflectors and sockets adapted to electricity, but usually they are designed for lamps with miniature base (diameter three-eighth inch, length onehalf inch), which are entirely unsuitable. The headlights should be fitted with standard Edison screw bases (diameter 1 inch), and the side and tail lamps with candelabra bases (diameter seven-sixteenth inch,

Adapter for Changing from Kerosene to Flectricity.

length five-eighth inch). Some headlights originally designed for acetylene can be modified for electricity, but great care must be taken to adjust the position of the electric lamp so that a suitable beam of light will be reflected upon the road. A slight change in the position will make a remarkable difference in the results.

Side lamps and tail lamps designed for

BATTERY FOR LIGHTING AND IGNITION.

electricity may be much simpler in form and construction than lamps for kerosene, and while the latter may be adapted to electricity they include unnecessary parts, such as burner and oil reservoir.

#### BATTERY.

Tungsten automobile lamps will have satisfactory life at an efficiency of 1 watt per candle. On this basis the required battery capacity may be readily calculated. Two 16 candle power headlights, two 2 candle power side lights and one 2 candle power tail light require about 38 watts, or, with a 6 volt battery, the current will be about 6.3 amperes. A 100 ampere hour battery will supply all these lamps continuously for fifteen hours without recharging. The lamps are so readily turned on or off that motorists will generally not use the headlights except outside of town, and the side

SIDE LIGHT.

lamps can then be extinguished. The number of hours of service with one charge will thus be considerably prolonged.

The battery is also available for engine ignition. It may be recharged on any direct current system, or from an alternating current system with a mercury rectifier, or any device used for charging ignition batteries.

An electric system of automobile lighting requires much less weight in battery than is commonly supposed. A 100 ampere hour battery weighs 55½ pounds, but it replaces the ignition batteries weighing

HEADLIGHT.

SIDE LIGHT.

TAIL LIGH

TUNGSTEN AUTOMOBILE LAMPS.

probably 25 pounds and a gas tank weighing 30 pounds.

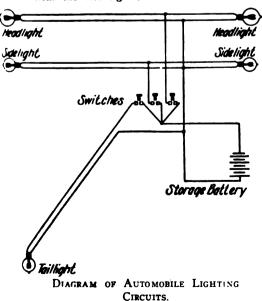

#### WIRING.

The lamps should be connected on three separate circuits, one including the two headlights, another the two side lamps, and the third the tail light. This arrangement permits the use of headlights and tail light for touring where the side lamps are not required, and in the city the side lights and tail lamp can be used without the headlights. The wire must be heavy enough to carry the current without appreciable drop in voltage, and should be connected to the battery through a suitable fuse. Wire-

HEADLIGHT.

men are liable to overlook the fact that low voltage lamps are very sensitive to a drop which would be entirely permissible with 110 volt lamps. The battery leads and wires leading to the headlights should have a cross section of not less than 10,000 circular mils (No. 10, B. & S.). The wire for side lights and tail lamp may be smaller -say 4,000 circular mils (No. 14, B. & S.). Flexible wire should be used, and on expensive cars it may be enclosed in brass piping so as to entirely eliminate any possibility of damage from short circuits. A short length of rubber tubing should be used, however, to connect the brass pipe with the headlights, as otherwise the vi-

TAIL LIGHT.

bration may cause trouble. If a car is carefully wired with well insulated wire, it will be perfectly safe without the brass piping, which, of course, adds considerably to the expense.

As previously stated, the headlights should be fitted with standard Edison screw sockets (I inch diameter), and the side and tail lamps with candelabra sockets (seven-sixteenth inch diameter). The miniature sockets (taking a base of three-eighth inch diameter) frequently used for this purpose are entirely too small to carry the current and withstand the vibration. The switch must be adapted for at least three separate circuits, and it should be conveniently located on the dash within reach of the driver. Additional circuits are a convenience for a small lamp over the speedometer, a portable trouble lamp (4

Four Circuit Switch for Automobile Lighting.

candle power), and a lamp of about 2 candle power conveniently located for the inspection of maps or road books. Switches of the type shown in the illustration are made up for various circuits from one to four.

# COST.

The cost of equipping a car with electric lamps depends, of course, upon the material selected and the charges of the wireman employed. The following will serve as a rough approximation:

One 100 ampere hour 6 volt battery	\$35.00	
One battery box for running board	5.00	
Two 16 c. p. 6 volt tungsten lamps	1.00	
Three 2 c. p. 6 volt tungsten lamps	1.50	
One three or four circuit switch	1.50	
Fifty feet twin conductor	2.50	
Wireman's time, one day	3.00	
,	\$40.50	

The cost of brass lamps has not been included in the estimate, because it is substantially the same as for gas and oil lamps.

The cost of two standard and three can-

delabra sockets, which will be required if gas or oil lamps are modified for electricity, is about \$1.50.

#### SUPERIORITY.

The small 2 candle power tungsten side and tail lamps will give a brilliant light never seen in kerosene lamps, even when new, and as there is no soot or heat to damage the glass and reflecting surfaces, and no deterioration, the brilliancy will be permanent. Electric lamps cannot blow out. The 20 candle power tungsten headlights, when properly adjusted with reference to the mirror, will fully equal the best acetylene lamps.

For safety and convenience electric automobile lamps are unsurpassed, and will speedily be included by manufacturers as part of the standard equipment of all high grade cars. They are equally advantageous for motor boat lighting.

# Convention of Maxwell Branch House Managers.

The 1909 convention of the district supervisors and branch house managers of the Maxwell-Briscoe Motor Company went into session on July 13 at New Castle, Ind., where the largest of the company's factories is located. Most of the delegates arrived from Detroit, where they had gone to attend the festivities incident to the start of the Glidden Tour. The party left Detroit on a special train of the Big Four, stopping for luncheon at Springfield, Ohio. The first day's session was attended only by district supervisors and district managers, and the discussion included the selling policy of the company for the coming season. After the first day's work the Maxwell men were the guests of the city of New Castle, which had prepared an elaborate entertainment at the Country Club, otherwise known as the Nip and Tuck Club. Fireworks, band concerts and general jollification at Maxwell Park were attended by some five thousand New Castle inhabitants. In the second day's meeting Maxwell dealers also took part.

## Weston-Mott New Building.

The Weston-Mott Company, of Flint, Mich., has decided to erect another new factory building for the manufacture of automobile rims and hubs. The building will be 500 feet long by 75 feet wide, and two stories high, which together with the basement gives an aggressive floor area of 110,000 square feet. The company located in Flint about three years ago, removing there from Utica, N. Y. It now employs about 1,000 men, and after the new addition is completed it will give employment to about 1,600.

# New Detroit Company to Produce Cheap Runabouts.

A new company has been organized in Detroit, to manufacture a \$500 runabout. It is known as the Demotcar Company, and has offices in the Bailey Building, on Twenty-first street.

# COMMUNICATIONS

## Exhaust Horns.

Editor Horseless Age:

Along with the development of the automobile engine it is interesting to note the different devices for utilizing the exhaust for signal blowing.

These devices may be divided into two classes—those attached between engine and muffler and those attached in the rear of the muffler. Up to very recently the former type prevailed, principally because of the persistent idea that only forward of the muffler could there be secured an exhaust sufficiently powerful to sound a horn under all conditions of speed.

Another factor that has prevented, or at least discouraged, the use of rear of muffler exhaust signals has been the marked variation in the type of muffler used by different makers—some delivering a powerful exhaust at the end of the rear exhaust pipe, while others almost entirely vitiated the power of the gases.

While the foregoing has been an obstacle in the manufacturer's path, the car owner has cherished his own objection, namely, that at low speed, such as would be used for city driving, there was not force enough to the exhaust to sound the signal, however well it might operate at higher speed on country roads.

This condition was due entirely to the fact that the manufacturer of signals was trying to make one size of signal serve for all sorts of cars, from one cylinder to "big sixes." Obviously this was futile, to say nothing of the attempts to adapt one horn to all types of mufflers.

More recently one manufacturer had the perception to bring out four graduated sizes of a unique type of rear of muffler exhaust horn. Some one of these four sizes adapted itself to any sort of car where the construction allowed room to locate the device. As was to be expected from previous experience, too small a size, while operating nicely at low speed, either shrieked or "blew out" at high speed. The reverse was true of too large a size, which gave a pleasing, far reaching tone at high speed, but failed altogether to sound at low speed.

This clearly proved the necessity of adapting the size of horn to the action of the exhaust on a given car. The normal horn uniformly gave excellent results at all speeds.

Right in the midst of this consideration the question naturally arises, Why use the rear of muffler exhaust horn at all?

The answer lies in the very considerable expense of the cut-out device into which the between engine and muffler types of signals are screwed, the large item of time

and labor involved, and the frequently necessary marring of the car.

Another serious objection to some makes of the cut-out type of signal is clogging by particles of carbon to such a degree that the sound ceases entirely or is weak. This feature necessitates taking apart and cleaning the device.

This trouble is not, however, a feature of all the cut-out signals. For instance, the very type referred to above as having been successfully adapted to use in the rear of mufflers was modified by the manufacturer to use in connection with the cut-out devices.

The construction of both is such that it is quite impossible for carbon particles to clog them.

This advance in the use of exhaust blown horns at least gives the motorist a choice, and with a tendency to standardize parts the rear of muffler type will doubtless be more and more in favor as time goes on.

H. L. H.

# Queries.

Editor Horseless Age:

What is meant by special hardened air furnace iron for cylinder castings?

Can any material other than cast iron be used for cylinders? Could steel tubing or steel castings be used to advantage building a light weight motor?

Why are marine motors operated at slower speed and built so much heavier than auto motors?

[The air furnace is distinguished from the blast furnace in that the fuel whose combustion melts the iron, instead of being mixed with the broken pig iron, is entirely separated from it. The iron is placed in a retort and is melted by applying heat to the retort externally. The term "special hardened" means presumably what it says. We have, of course, no means of telling how this special hardening is accomplished.

Steel cylinders have been used for racing motors, but were given up again. It is very difficult to make a permanently water tight joint between a steel cylinder and the jacket, and the bearing properties of the steel are not as good as those of cast iron. The unequal expansion of a cast iron piston and a steel cylinder is another disadvantageous feature. The consensus of opinion at present seems to be that for motors that have to operate continuously, that is, for service motors, cast iron is the best cylinder material, all things considered.

That marine motors are built to operate at lower speed than automobile motors is largely due to the fact that motor boat owners are not as much possessed with the speed craze as automobile owners. A slow speed motor will last longer than a high speed motor, but if you wish to be able to pass everything in sight, whether on the road or on the water, you must perforce use a high speed motor, because such a motor weighs less than a slow speed motor, and therefore does not need such a heavy support (running gear or

hull). For commercial vehicles, which are not required to run at high speed, low speed motors are also coming to be used. There is one other reason, however, why automobile motors should be run at higher speed (and so made lighter) than marine engines. The automobile engine and its supporting frame are carried on pneumatic tires, which are very sensitive to weight, their rate of wear increasing rapidly with the degree of loading. There is no corresponding increase in wear and expense with increase in weight in the case of motor boats.—ED.]

# Elevating the Chauffeur's Calling. Editor Horseless Age:

The exact status of the chauffeur in a country like this, supposedly without class distinctions, is and has been a mooted point. and much discussed. While the large cities have developed a class of men like the old coachmen, to whose employers the imporance of wearing a livery well and saluting properly is greater than the ability to care for a machine, it is still true, I think, that the majority of chauffeurs throughout the country are a wideawake, elever lot of young men, who take their vocation seriously, and are entitled to a good place socially. When the personal equation makes it possible, they should be given the standing of men in charge of other expensive power plants, electricians, etc., and should be trusted as far as the individual proves he can be. In these days of more perfect machines, garages conveniently situated for repairs and better tire equipment, the average chauffeur finds more idle time on his hands than formerly, and there is where the employer can do most to benefit the man. Keep him at work as steadily as possible, encourage him to take an interest in studying his machine thoroughly and keeping it up to its highest efficiency, and take an interest in him as a man and a fellow citizen, and if he is any good you will improve him and he will take naturally the place in the social scale he is entitled to. If he isn't any good, try for a better one. There are many young men of good American families taking up the profession, and they should be encouraged by giving them opportunity for self improvement, and not discouraged by blaming the vocation for the scamps who are undoubtedly in it.

HENRY P. BENSON.

# Ignition Query.

Editor Horseless Age:

Can I successfully use two spark plugs and insulate the first one in the circuit from the engine and get a spark from both? Would the spark from the second one come in time to appreciably hasten the combustion if the plugs were set opposite in the firing chamber? Would there be any bad effect on the ignition system if this was done, or would the voltage or amperage have to be increased? C. L. EDWARDS.

[We presume that what you have in mind

nnect the two spark plugs in series. y the best plan of accomplishing this se a coil in which the secondary is not connected to the primary inside the coil, so that you can th ends of the secondary windsulated from the frame. You n use two ordinary spark plugs, and one end of the secondary winding sulated terminal of one of the plugs other end of the secondary windhe insulated terminal of the other The spark will then jump from the d terminal of the first plug to the d terminal, and from the grounded of the second plug to the insuminal of this plug, and then return coil. The two sparks occur simuly. The above connections are for cylinder engine, or where one coil ded for each cylinder, in case of a inder engine. This arrangement e easier to carry out than that sugby you, as to connect a spark plug e cylinder by means of a fitting of g material would entail consideraiculty. The two spark plugs in ould, of course, require a higher than only a single spark plug; in actically twice the voltage.-En.]

# Cleaning the Radiator.

HORSELESS AGE:

you kindly tell me what to use to e dirt and scale out of a radiator, amount per gallon?

S. K. SINGER.

lean the radiator of dirt and sedie whole of the water in the radiat be run out and measured, taking at no water is left which would e effect of diluting the solution. er is made by dissolving 21/2 pounds caustic soda so that it makes I galolution. Considerable heat is genwhen the soda is dissolved, and fretirring is necessary. After the licooled the radiator may be filled and it is left in all night and run he morning. Caustic soda will corminum and zinc, and if any part of ator is made of these materials it not be used. After running out the lution the radiator should be thorrinsed; by means of a hose conto a hydrant, for instance,-ED.]

## on Spring in Steering Gear. HORSELESS AGE:

you kindly tell me in one of your issues whether or not any patents en issued on a steering gear with a spring in the gear, to take the f the ball sockets and to act as a bsorber? Also what would be your of a gear of this type?

ALBERT BRAUN.

do not remember ever having seen into of a gear so cushioned, but say positively whether or not such has been patented, as this would a search of the patent records,

which we cannot undertake. We should think it to be considerably more difficult to incorporate a suitable cushion spring in the steering gear than in the ball and socket joints, and for this reason would not think as favorably of the plan as of that usually followed.—Ep.]

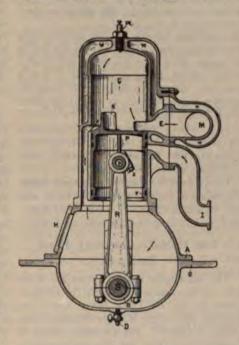

# Missing in Two Cycle Motor.

Editor Horseless Age:

I have a two cylinder, two cycle, three port valveless engine, 4½x4½ inches, of 15 horse power. The same runs very nicely under load at any speed from 100 revolutions up, but if I let it run without any load I notice constant misfiring and knocking, and sometimes if I change from high to low speed there is a crank case explosion. I have tried out three different makes of carburetors, and the trouble is the same with all. Will you tell me what the cause may be?

O. W. Brown.

[When the engine is closely throttled only a small amount of charge is transferred

from the crank chamber to the cylinder, and the scavenging effect is then much smaller than when the engine is operating at full power. A considerable volume of burnt gases remains in the cylinder, and as these gases are hotter and lighter than the new charge they will occupy the uppermost portion of the cylinder, where the spark plug is located, and the spark will then occur in dead gases and there will be no explosion. This trouble could be remedied, to some extent at least, by placing the spark plug in the side wall of the cylinder directly above the transfer port, and as low as possible without being struck by the piston.

Explosions in the crank case are liable to occur with any two cycle motor that has a direct transfer passage from the crank chamber to the cylinder. They generally occur when the mixture is for any reason unusually lean, as when the speed of the motor is suddenly pulled down. This trouble can be overcome by placing a screen of fine mesh wire gauze in the transfer passage. Of course, these changes are difficult to make in an engine already built, but if you have the patterns you can change them to allow making these alterations in the construction of the engine.—Ed.]

# Criticises the Block Motor.

Editor Horseless Age:

The first question is, what is gained by such construction, and do the defects disappear because some few concerns care to adopt it?

I consider that the practice is not based on good judgment from any standpoint. The extra risk in the foundry means much; a defect may develop that means that four cylinders have to be "scrapped," and this may occur at any place from the foundry to the user. A cut cylinder bore due to lack of care and proper lubrication means expensive repair bills. The practice of dispensing with inlet and exhaust pipes seems to me ridiculous, for several reasons. Take the inlet pipe. Is it possible to get a uniform charge in all four cylinders? With the front cylinder we have a gas heated by the exhaust gases from two cylinders, while the rear cylinder charge is heated by contact with the heat of all four, and no one of the four can be expected to receive the same amount of heat. Then, again, knowing that a large percentage of the total heat of combustion must pass off through the exhaust valves, why confine the gases after all the useful work is done? It will only tend to distort the cylinders by the unequal heat effects just referred to. The practice also requires the provision of additional radiator surface to absorb the heat that could otherwise be expelled in the usual way. I consider this subject well worth investigation. I am like many others, I want to be shown.

[You mention only the disadvantages of the block construction and do not say a word about the advantages, such as reduction in weight, greater simplicity, fewer joints, etc. We will not go into details, but will leave it to some champion of the block motor to draw attention to its various merits.—ED.]

# Relative Fuel Economy of Six and Four Cylinder Motors.

Editor Horseless Age:

Will a six cylinder engine use any more gasoline than a four cylinder of equal power? I have heard this stated so many times that "I ask to know."

What records have six cylinder cars made in any of the numerous economy tests held over the country?

BEVERLY B. HOBBS,

[There is exceedingly little data on this point, insufficient to warrant generalization. The only logical basis of comparison is the pound-mile or two-mile basis. In the earlier fuel economy contests the weight

of the cars with passengers was not taken into account. As regards these contests it is sufficient to say that none was ever won by a six cylinder car. In the One Gallon Contest held by the New York Trade Association in May of this year two six cylinder cars competed, viz., an Overland "38" and a Lozier "51." The pound-mile score of the former was 53,500 and that of the latter 89,433, making the average 71,467. If we take all the four cylinder cars of 24 horse power and over that competed in this contest we find that the average poundmile score was 67,620. Consequently the average of the "sixes" is somewhat better than that of the six "fours" of 24 horse power and over. According to this test, therefore, the six cylinder motor is more economical of fuel than the four cylinder, but, as stated above, a single test is not conslusive.

The supposition that six cylinder motors are less economical of fuel than four cylinder ones undoubtedly has its foundation in the fact that six cylinder cars in general have more power in proportion to weight to be moved than four cylinder cars, and must, therefore, be more closely throttled in traffic and wherever speed limits must be observed, and the more an engine is throttled the more wasteful of fuel it is. We believe that taking two engines of the same horse power, one six cylinder and the other four, but otherwise of identical design, then the fuel economy at full load will be practically the same for both. —ED.]

## Heating Private Garage.

Editor Horseless Age:

Will you kindly answer these questions in your valuable publication?

- I. Is it safe to heat a frame building, 18x24 feet, and used as a private garage, by means of a coal stove during the winter months, when doors and windows are closed?
- 2. If not, what is the danger, and how can I heat the garage so as to safely keep a gasoline car in it?

C. L. AMBOS, M. D.

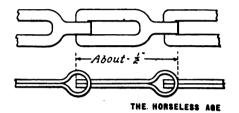

[It is not safe to heat a frame garage (or any garage) by means of a coal stove inside the building. There is always some danger of gasoline leaking from the car, and the gasoline vapor which would then form would travel along the floor and reach the stove and become ignited. It is quite conceivable that a slight leak may develop in the gasoline piping, during a drive, which remains unnoticed when the car is put in the garage, and an explosion would then almost be certain to result. The proper method of heating a small garage is by placing a heater (steam, hot water or hot air) in a separate room or lean-to outside the garage, and to put either steam pipes or hot air pipes in the garage. There must be no opening in the wall between the heater room and the garage, except for the pipes to pass through.—Ep.]

# New Method of Decarbonizing Cylinders.

Editor Horseless Age:

I have read a good many articles on "how to remove carbon" of late in your valued paper, and it occurred to me that I might submit a method I have been using for the past two years with good results.

Take the car, after it has been put away for the night, and put about two tablespoonfuls of coal oil into the cylinders and allow it to stand over night. Then, in the morning, procure some soft brass chain, as shown in the sketch, and cut off a piece not longer than twice the diameter of the cylinder bore minus I inch; fasten the ends with a piece of soft brass or copper wire and drop in

the cylinder on top of the piston, being careful to make it lie in a circle and not in a tangle. Now start the motor with everything regular, being careful not to run it too fast. About five minutes will clean the cylinder head and walls, as well as the piston head, in fine shape.

It is obvious this method will only work on vertical engines, and that it will only clean that part of the motor cylinder which is directly above the piston.

I have used this method on several different makes of engines and have never noticed any injurious effect. E. W. Jones.

# The E-M-F Company Buys De Luxe.

The latest large deal to attract the attention of the automobile world is the purchase of the De Luxe Motor Car Company by the Everitt-Metzger-Flanders Company, of Detroit. The De Luxe factory is situated at Clark and Jefferson avenues, Detroit. It is close to the water front and has splendid shipping facilities. The factory site comprises some 15 acres, about half of which is covered with buildings which have been devoted to the manufacture of the Car De Luxe.

The entire property of the company, including land, buildings, machinery, patents, drawings, tools and fixtures, is included in the deal. It is said that the purchase was for cash and that the price was somewhere between \$750,000 and \$1,000,000. Besides the property of the De Luxe Company the E-M-F Company purchased from Messrs. Kaufman an adjoining tract of about 4 acres, close to the new plant of the Timken-Detroit Axle Company.

The E-M-F Company will use their new purchase for the manufacture of a smaller car, which will be known as the "Studebaker-Flanders 20." Much of the present

equipment of the De Luxe factory will be suitable for this purpose, and the additional special machinery and materials necessary are already ordered. Indeed, plans for the manufacture of the new car are far enough advanced so that 150 men were put at work in the new factory last Friday.

Present plans provide for the production of 25,000 Studebaker-Flanders "Twenties" during the calendar year 1910, deliveries to begin Jauuary 1, 1910. The manufacturing equipment will be more complete than any yet installed in an automobile factory. The details of the new car have not yet been announced, but it is currently reported that it will have a "block" motor, will be furnished with a high grade magneto, and in fact with a high grade equipment throughout. The price will be less than \$750. Mr. Flanders states that the company will make a limited number of the Car De Luxe.

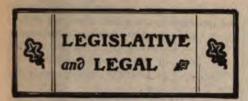

In connection with this new acquisition of the E-M-F Company, it may be well to state definitely the status of the company, which is somewhat confused in the minds of many in the trade. The E-M-F Company is wholly a manufacturing concern, and is under the direction of Walter E. Flanders, who is president. A large interest in it is held by the Studebaker Automobile Company, which markets the cars in all parts of the world, the present product being known as the "Studebaker E-M-F Thirty." Indications at the factory where the "Thirties" are made point to immediate extension in the manufacturing facilities, to take care of the increasing demand for these cars.

# Atlanta Show Plans.

S. A. Miles, general manager of the National Association of Automobile Manufacturers, arrived in Atlanta, Ga., on July 14, to make arrangements for providing increased space for the automobile show which is to be held in the Auditorium-Armory in Atlanta, November 6 to 13. Mr. Miles states that he has applications for twice as much floor space as is available in the Auditorium, and that steps must be taken to accommodate the would-be exhibitors. It is proposed to close Courtland street immediately in front of the show building and enclose the alley on two sides of the building to provide additional room. A petition to close the street is to be presented to the streets committee of the Atlanta council.

# Brush Runabout Plans.

The Brush Runabout Company, Detroit, Mich., has had plans prepared for a new factory building 871x150 feet, which is claimed to be larger than any single factory building devoted to automobile manufacture at present. The company plans to turn out 2,000 of its runabouts next year, and will make very few changes in design of the car. Orders have been given for \$80,000 worth of new machinery.

# Jail for Speed Maniacs.

In an endeavor to stop reckless speeding through the streets, the city council of Los Angeles has passed an ordinance imposing a straight jail sentence of at least ten days upon any driver of a motor car found guilty of violating the speed regulations, provided his machine exceeded 30 miles per hour. For a second conviction of speeding at 30 miles or more per hour the minimum penalty is thirty days, and for the third and subsequent convictions a sentence of 100 days may be inflicted. By establishing a speed of 30 miles an hour as reckless and dangerous driving the council, in consultation with representatives of the A. C. and the Los Angeles dealers, hoped to distinguish between motorists guilty of technical or lesser violations of the law and that class of drivers responsible for the average of five accidents per day that stirred up the agitation for the straight jail sentence. The speed limits were not reduced, but the minimmm fine for violations of the traffic rules was raised from \$10 to \$25.

While the new ordinance makes it imperative for the magistrates to impose a jail sentence upon drivers whose cars exceed 30 miles per hour, such sentences, in all probability, will be few and far between, and still fewer of those sentenced will serve their time. The usual difficulty of legally proving a high rate of speed will interfere. Besides, the city council so far has refused to purchase more and faster motorcycles than the two slow machines now in use by the police, and the chief of police has declined the offer of the A. C. to have 200 of its members appointed special officers. The chief was of the opinion that every driver arrested for speeding would display a star and explain that he was going fast in order to overtake and arrest another fellow.

# Legal Decision Regarding Motorist's Responsibility.

The question of the rights of motor vehicles on the public highways has been decided by C. L. Baldwin, of the Justice Court at La Crosse, Wis. The decision was given in the case of Edward Wimmer, a grocer, against Miss Mae Williams, to recover \$50 damages, and was in favor of the defendant.

The point involved was: How close to a horse, tied at the roadside, may a motor vehicle go without making the driver guilty of negligence in case of accident? The testimony showed that the car was being driven at a moderate pace, under its own momentum, the engine being dead, and when passing the horse was but 3 feet away from it. The horse broke away, but a bystander grasped the bridle. At this juncture Mr. Wimmer appeared and demanded damages

for the damaged piece of harness. The plaintiff's attorney set up the claim that as the car was as close as 3 feet to the horse the driver was responsible, this constituting negligence. Mr. Wimmer and other witnesses testified that the horse was "city broke" and not unusually frightened when near motor vehicles.

The case is so unusual that appeals will be made to higher courts to determine the correctness of the decision.

# Recent Decisions.

REAR COLLISION ON WELL LIGHTED STREET.

Where a wagon on the right hand side of the road was struck by an automobile from the rear, and the road was lighted sufficiently to enable the wagon to be seen for 150 feet, a judgment for damages was proper. The fact that the wagon carried no light was held immaterial.—Decou vs. Dexheimer, N. J., 73 Atl. 49.

QUESTION FOR THE JURY.

The negligence of a street railway company was held to be a question for the jury where a street car collided with an auto at a crossing, where the speed of the auto was not more than six miles an hour and the car was running under full headway without any signal.—Loomis vs. Brooklyn H. R. R. Co., 117 Supp. 292.

# A. C. A. in Uniform Law Movement.

President E. H. Gary, of the A. C. A. has appointed George F. Chamberlin, Colgate Hoyt, Henry H. Law and V. Everit Macy members of a committee to formulate plans for a conference between members of the State Legislatures of New York and the New England States to discuss uniform State laws. A plan is to be prepared which will embody suggestions of proposed uniform laws for presentation to the conference on uniform laws which has been called by President Taft to meet in Washington this year.

# New Jersey Physicians Not Exempt from Speed Law Requirements.

Physicians are not exempt from the requirements of the speed limit provision of the New Jersey automobile law. State Motor Vehicle Commissioner Smith has summoned Dr. Chas. Miller, of Riverton, to answer to a charge of driving his automobile at an unlawful speed. Commissioner Smith says that no physician has any right to a higher rate of speed than any other motorist. Should a physician respond to an emergency call at a high rate of speed his explanation would be listened to, but an explanation he must make.

## Opposition to Connecticut Bill.

Considerable opposition is being developed in Connecticut to the automobile bill recently passed by the Legislature of that State, and which is now awaiting the signature of the Governor. An effort is being made to induce the Governor to veto the bill. The Connecticut State A. A. has sent

out a circular letter in which various alleged defects of the bill are pointed out. It is held that the bill is full of errors and difficult to understand; that the scheme of taxation is unjust and that no penalties are provided for violations of various provisions, so that it would be impossible to enforce these. The provision of the old law which enables the owner to offer his car as security for bail is omitted in the new law, an omission which is strongly objected to by the motorists.

# Legal Notes.

The Mount Desert automobile exclusion act has been ratified by all of the towns on the island with the exception of South West Harbor, in which three automobiles are owned.

A test of the new Illinois State law is to be made by Dr. John W. Tope, Jr., of 150 Lake street, Oak Park, Ill. Mr. Tope's lawyers state that they have found serious flaws in the new law.

John C. Kaiser, of Jersey City, a former sheriff, has been appointed Jersey City agent of the State Motor Vehicle Department by State Automobile Commissioner J. B. R. Smith. Kaiser succeeds Joseph Gallagher, who was killed in an automobile accident on May 16 last.

Acting Mayor Patrick F. McGowan, of New York city, has vetoed the ordinance requiring municipal automobiles to be sign marked in large letters. The reason assigned by him is that such marking would interfere with the work of the police and health departments.

Coroner C. K. Henzler, of Toledo, Ohio, has given out a notice that hereafter if he is called upon to investigate the death of a person run down by an automobile that was driven beyond the speed limit, or because of the driver not exercising sufficient caution at street crossings, he will be justified in holding the guilty driver to the grand jury for criminal negligence.

An ordinance went into effect on July I in Charlotte, N. C., requiring automobilists to pay an annual city license tax of \$5, and chauffeurs a tax of \$1, and requiring all State licenses to be registered with the city treasurer. So far very few owners of cars in the city have complied with the ordinance, and there is said to be much opposition to it, it being claimed that the tax is unconstitutional, as it amounts to double taxation.

## Obituary.

George T. Robie, president of the Excelsior Supply Company, of Chicago, died in that city as the result of an operation for appendicitis on July 18. Mr. Robie was born in Walworth, N. Y., on March 26, 1853. He went to Chicago in 1873 and established the Excelsior Supply Company in 1876. Since then he had been prominent in the work of the Association of Commerce. He leaves a widow and one son, Fred T. Robie.

# Commercial Applications.

Motor Delivery Wagons for Indianapolis Library.

The Indianapolis Public Library is arranging to adopt automobiles for delivering books from the main to the branch libraries. At a recent meeting the Board of School Commissioners having the library in charge instructed John E. Cleland, business director, to obtain prices on such vehicles. Andrew Carnegie has contributed \$120,000 for the erection of six branch library buildings, which will make the present horse drawn delivery inadequate.

# Motor Mail Collection Test in Buffalo, N. Y.

Buffalo, N. Y.

Tests made by the Buffalo, N. Y., Post Office during the past two months are said to have shown that one automobile and one collector can collect as much mail as two horses, two wagons and two men, and Postmaster Greiner at the completion of the test, at the end of this month, will recommend to the department at Washington that the present collecting equipment, consisting of eleven horse wagons and horses, be replaced by five automobiles.

## Commercial Notes.

Hannes Lawson, a drayman of Rockport, Ill., has placed orders for two motor trucks.

An automobile service has been inaugurated between Allegan and South Haven, Mich. One round trip is made per day.

George H. Prouty, the proprietor of the last horse stage line in Massachusetts, on July I replaced his equipment with motor cars. The line extends between Petersham, Barre and other nearby points; it carries the mails and passengers, and has been in operation for nearly a century.

Arthur Kingery, a produce dealer at Mohawk, Ind., has had a special automobile delivery wagon built by an Indianapolis concern. He formerly drove an old time huckster wagon, going through the rural districts buying butter, eggs and other produce. The old vehicle has been discarded for the automobile, which he also uses for hauling his purchases to the Indianapolis market, thus saving freight bills.

The Atlantic City, N. J., police department has purchased a motor police patrol from the Olds Motor Works. The new patrol will have a capacity for twelve passengers inside and two on the front seat; will have a cage body and top, and be equipped with a four cylinder, 40 horse power motor. The wheel base will be 132½ inches, the wheels 36 inches all round, and the car will have a speed of 40 miles per hour.

Thomas Halloran, a rural mail carrier of Bennington, Vt., whose work requires him to cover a distance of 40 miles every day, some time ago purchased a motorcycle

for use on his rounds, but soon found that the time required to find a suitable place in which to stand the machine at each house where deliveries were required made the use of the machine inconvenient, and now Mr. Halloran has adopted the automobile. He is said to be the first rural mail carrier in Vermont to use the new means of locomotion.

# New York Taxicab Rates Cut.

Last Monday the New York Taxicab Company inaugurated a reduction in the tariff for its red taxicabs to 30 cents for the first half mile, and 10 cents for each additional quarter mile, for one to four passengers. This rate is the same as was charged when the red cabs were first put into operation. In the original announcement of the reduction in the newspapers. owing, it is said, to an error of an advertising agency, it was stated that a charge of 10 cents would be made "for each additional half mile" (instead of quarter mile), and this erroneous announcement caused quite a stir in taxicab circles, and led an independent cab owner to make the assertion that the company could not possibly live at such rates and would be obliged to raise the rates again after it had crushed out the independents.

# Cleveland Taxicab Consolidation.

The Citizens' Taxicab Company, of Cleveland, Ohio, on July 13, bought the stock, fixtures and good will of the Studebaker taxicab service. The Citizens' Taxicab Company will have its headquarters at 1004 Prospect avenue, S. E., where it will maintain its principal garage. A station will be established at Euclid avenue and East 105th street. The company now operates fifteen taxicabs, and promises to put on fifteen more soon. Six cabs were taken over from the Studebaker Company. The officers of the company are: S. W. Harding, president; J. H. Foster, vice president; Benj. A. Gage, secretary, and J. D. Ludlow, treasurer.

# D. M. Parry Organizes Auto Company.

An automobile factory is to be established in Indianapolis, as soon as buildings can be erected, by a company that is being organized by David M. Parry, a well known manufacturer of carriages. Until recently Mr. Parry was president of the Parry Manufacturing Company, manufacturing carriages, but resigned, retaining his interests in the concern.

It is probable that the new company, which will be known as the Parry Automobile Company, will have an authorized capitalization of \$1,000,000. The factory buildings alone will cost approximately \$100,000, and are to be erected as soon as a satisfactory site can be obtained.

Mr. Parry states that the cars to be manufactured will be known as the Parry, and

that for the first year the line will consist of two models, one a two cylinder runabout to sell at \$1,250, and the other a four cylinder, 30 horse power, five passenger touring car. Some of the machinery has been ordered, and the first cars will be ready for the market during the fall.

Mr. Parry is not unknown in the automobile field, having been one of those who reorganized the Overland Automobile Company, prior to its last reorganization, when J. N. Willys became president. It is understood that Mr. Parry disposed of his interests in the Overland Company some months ago.

#### Reo Plans.

The Reo Motor Car Company, of Lansing, Mich., is this year for the first time bringing out a four cylinder car. The cylinder dimensions are  $4\times4\frac{1}{2}$  inches, and the cylinders are cast in pairs. Among the other features of the new car are an I beam front axle, overhead valves, 108 inch wheel base, selective type of change gear, high tension magneto and a multiple disc clutch. The control of the car is on the left hand side. The company plans to turn out 10,000 cars during the coming season, including a number of the present two cylinder models.

#### Mitchell 1910 Models.

The Mitchell Motor Car Company, of Racine, Wis., will produce three models the coming season, viz., a 100 inch runabout, a four cylinder, five passenger touring car, and a seven passenger, six cylinder touring car. The cylinders of all the models are of 41/4 inch bore by 5 inch stroke, so all cylinders, pistons and connecting rods will be interchangeable. A magneto is a regular equipment on all cars. The motors all have overhead valves, and are said to be very quiet running. Among the special features of the new models are a tubular torsion bar, a straight line drive, a single universal joint, lower hanging of the body and a floating type of rear axle. The company is arranging for a production of 6,000 cars the coming year.

# Jackson Line for 1910.

The Jackson (Mich.) Automobile Company's line for next year will comprise three four cylinder models, selling at \$1,250, \$1,700 and \$2,250, respectively. The smallest car is rated at 20 horse power. The changes for next year include larger wheels and tires and a longer wheel base.

Oakland 1910 Output.

The Oakland Motor Car Company, of Pontiae, Mich., which is now controlled by the General Motors Company, plans to turn out 3,000 cars during the coming season, its line including a 20 horse power, two cylinder car, and a 40 horse power, four cylinder, the latter selling at \$1,700. Few changes will be made in the models for next year.

# MINOR MENTION

The Gray-Hawley Manufacturing Company, Detroit, Mich., will soon erect a new factory.

The Heinze Electric Company, of Lowell, Mass., have completed an extensive addition to their No. 1 plant.

The referee in bankruptcy for the Pneu l'Electric Company, New York city, has declared a first dividend of 5 per cent. on all allowed claims.

The Widmer Machine Works, of Detroit, will remove most of their plant to New York. Mr. Widmer will remain in Detroit to look after that end of the business.

L. C. Van Bever and H. H. Knepper have secured the agency for the New England States, with the exception of Connecticut, for the Standard Tire and Rubber Company.

It is reported that the Ford Motor Company, of Detroit, are now turning out their Model T cars at the rate of 450 to 500 a week. During the month of June 1,954 cars were shipped.

The Bosch Magneto Company, of New York, have recently secured additional space and reorganized and enlarged their office force to cope with the demand for magnetos for the 1910 season.

The new plant of the Rider-Lewis Motor Car Company, in Indianapolis, Ind., is nearing completion, and the company will begin in a few days to ship machinery from its Muncie factory to Indianapolis.

In our issue of June 30 the Lozier 45 horse power car was erroneously described as having cylinders of 51/6 inches bore by 53/4 inches stroke. The actual dimensions of the cylinders are 53/8 by 51/4 inches.

The Rapid Motor Vehicle Company, of Pontiac, Mich., has had plans prepared for an addition 670x60 feet in dimensions and another 300x60 feet. The company will install \$100,000 worth of machinery during the next four months.

A minor improvement in the 1910 Lozier models consists in an improved air pressure check valve replacing the old type of ball check, which latter required more or less frequent cleaning, due to the formation of carbon 'and consequent clogging of the valve.

The Boston Fire Department recently put into service another motor propelled fire wagon, the second of its kind. The vehicle is stationed in the same fire house as the first one, in the Roxbury district. The two motor wagons will cover the entire southern part of the city.

The New Departure Manufacturing Company, of Bristol, Conn., inform us that they are installing new machinery to meet the demand for New Departure ball bearings, for which they have recently taken several important contracts for 1910 models. They have been working a night shift for some time.

The Hupp Motor Car Company, of Detroit, are said to be planning to turn out 5,000 cars in 1910.

The Whitney Manufacturing Company, Hartford, Conn., are making a specialty of chains for heavy trucks.

The Empire Automobile Tire Company, of Trenton, N. J., has opened an agency in Atlanta, Ga., at 117 North Pryor street, in charge of J. H. Young.

Childs & Ralston have established a tire repair shop on Philadelphia's "Automobile Row." Both members of the firm were formerly connected with the Diamond Rubber Company.

The negotiations of the Pietsch Auto and Marine Company, of Chicago, Ill., with the business interests of Kalamazoo, Mich., regarding location of a company in that city, have terminated unsuccessfully.

William E. Marengo, 207½ Chandler street, Worcester, Mass., has invented a new cushion tire for automobiles. He has applied for a patent on the tire, and will begin its manufacture in Worcester.

The Grabowsky Power Wagon Company, of Detroit, Mich., has recently increased its capital stock to \$300,000, and is negotiating for a new factory site, but plans to retain its present factory on Champlain

The Griffith Motor Company has been opened for business in Flint, Mich., at South Saginaw and East Court streets. The company will manufacture gasoline motors for automobiles. W. G. Griffith is at the head of the concern.

President J. A. Wister, of the Automobile Trade Association of Philadelphia, has appointed W. J. Foss and James L. Gibney members of the show committee, to make arrangements for the show which is to be held by the association next winter.

The new models of the Harry A. Haupt Company, New York, are nearing completion at the factory of the Bristol Engineering Corporation, Bristol, Conn. The line will include a four cylinder, 60 horse power model, and a six cylinder model of the same cylinder dimensions. The four cylinder models are expected in New York by the 1st of August.

According to Judge W. W. Slabaugh, who recently spoke before the Omaha, Neb., Young Men's Christian Association on "Our Country and the Young Men," "everywhere men are mortgaging their homes so that they can spin along the roads and wear green goggles. The automobile means the disruption of many a home, I fear."

The Palmer & Singer Manufacturing Company have introduced a number of changes in the new series of their "Six-Sixty" cars. The new model is known as the LXII, and is equipped with a motor of 47% inch bore by 5½ inch stroke, which is an increase in size over the former motor. Among the other improvements are a force feed oiling system, with leads to each bear-

ing, 36 inch wheels, and a multiple jet car-

Hack drivers of Montreal, Canada, have petitioned the police committee to prohibit the importation of taxicabs.

The tire manufacturers' branch of the Motor and Accessories Manufacturers will hold a meeting in New York city on July 27.

E. T. Birdsall, M. E., agent for Selden cars for Yonkers, N. Y., and Greenwich, Conn., has changed his address to 2230 Broadway. New York city.

John Heber, formerly of the Bates-Odenbrett Automobile Company, of Milwaukee, has established a gas tank recharging station on North Water street and Holton viaduct.

The Model Automobile Company, Peru, Ind., whose two additional buildings will be completed in about six weeks, recently had to resort to the use of tents for finishing cars, so as to be able to deliver on time.

The Waukesha Motor Company, of Waukesha, Wis., has awarded contracts for the new \$12,000 plant on St. Paul avenue, and work has commenced. The building will be 88x135 feet in size, of brick and steel construction.

The sale of the Columbia Electric Company, of Knightstown, Ind., manufacturers of the Leader automobile, is reported. The former owner was Moses Vanderbark, who has disposed of his interests to Earl Frost, of Greenfield, and Alonzo Thomas, of Willow.

Fred Sims, Secretary of State of Indiana, reports that 3,200 automobiles and motorcycles were registered in that State between April 1 and July 9, or considerably more than were registered during all of 1908. Mr. Sims estimates that the average daily sales of automobiles in Indiana by dealers amounted to \$32,000.

The Goodyear Tire and Rubber Company is again supplying each of the contestants in the Glidden Tour with an air bottle free of charge, the same as in former years. The Goodyear air bottles have recently been fitted with a new reducing valve, which can be set to give any desired pressure. It is claimed that no greater pressure than that for which the reducing valve is set can be obtained from the bottle, no matter how far the valve is opened or how long it is left open.

## Club Notes.

An automobile club is at present being organized in Tacoma, Wash. An organizing meeting was held at the Commercial Club on July 6.

The Board of Governors of the Lowell (Mass.) A. C. held a meeting on July 7, and appointed the committees for the carmival to be held at Lowell next fall.

Benjamin H. Marshall and Charles E. Fox, architects, have filed a bill in the Circuit Court at Chicago, to enforce a mechanics' lien claim against the Chicago A. C. Auxiliary Association for \$5,066.32, due for drawing plans, etc. for the chabbouse.

#### Terms of Cadillac Purchase.

While the sale of the Cadillac Motor Car Company stock to the General Motors Company for \$4,500,000 is said to have been on a cash basis, not all of the money was paid over at once. About 25 per cent. was paid down, and the General Motors Company has the option of paying the remainder in instalments in 30, 60 and 90 days, or sooner if it elects. The representatives of the General Motors Company say that the full sum will be paid in 30 days. In the meantime the stock is held in escrow by the Old Detroit National Bank, which will receive the payments and turn over the stock to the General Motors as paid for.

During the past week rumor had it that the General Motors Company were trying to get control of the Maxwell-Briscoe Motor Company, the Packard Motor Car Company, and the E. R. Thomas Motor Company. As usual, none of these rumors could be confirmed.

## Motorcyclists' Convention.

The national meet of the Federation of American Motorcyclists will be held in Indianapolis during the second week in August. It will be preceded by a two days' endurance run from Cleveland to Indianapolis. Originally it was intended to have the run over the route from Indianapolis to French Lick and return, but later the route to Cleveland-Indianapolis was decided upon. The endurance contest will be followed by the convention and three days' race meet on the new speedway at Indianapolis.

# Lowell, Mass., Auto Carnival.

The Lowell Automobile Club plans to hold a five day automobile carnival, beginning Labor Day, September 6, to consist of automobile, motorcycle and motor boat races. The races for small cars to be held on Labor Day will be for the Vesper Club trophy, the Yorick Club trophy, and the Merrimac Valley trophy. On the following Wednesday a cash prize of \$1,000 and the Lowell trophy will be competed for by cars having a piston displacement of 451 to 600 cubic inches, and a minimum weight of 2,400 pounds. The motorcycle races will be open to six classes, and will include a 100 mile race for the American championship, and 10 and 50 mile races for professional drivers.

# To Supply Parts for Wayne and Northern Cars.

L. A. Austin and A. O. Dunk, Detroit, Mich., have organized the Auto Parts Company, and have purchased from the Everitt-Metzger-Flanders Company the drawings and tools of the Wayne Automobile Company and the Northern Motor Car Company, whose models were discontinued when the Everitt-Metzger-Flanders Company was anized. The company will operate a ma-

chine shop at St. Antoine street and the Michigan Central Railway crossing and will supply spare parts for Wayne and Northern cars.

# Gary Locates at Muskegon.

The Gary Motor Car Company, recently incorporated by Alfred C. Gary, a nephew of the steel trust head, has decided to locate in Muskegon, Mich., the business men's club of that city furnishing a site and a factory building. Work is to be commenced at once on a one story brick building 400 feet long, which it is expected to have ready for occupancy by October 1.

## Tincher Bankrupt,

Thomas L. Tincher, of Chicago, Ill., one of the principal stockholders of the Tincher Motor Car Company, of South Bend, Ind., has filed a voluntary petition in bankruptcy, with liabilities amounting to \$48,359.57, and assets, aside from his stock in the automobile company, amounting to \$4,656.23.

# Garage Notes.

F. J. Cosford has opened a garage in Duluth, Minn., on Superior street.

The Missabe Auto and Machine Co. has been organized at Hibbing, Minn., with F. M. Smith as manager.

Joseph Coombs, of Marysville, Cal., has bought the garage of Capt. J. Rupert Foster on Second street, that city.

The Carondelet Auto and Machine Co., Carondelet, Mo., is erecting a one story brick factory building at 116 Robert avenue, at a cost of \$2,950.

J. D. Strutzel, Joliet, Ill., has taken the agency for the Mitchell line, and will shortly open a garage at 104 Jefferson street, which was formerly occupied by the Kinnel Auto Co.

The Girard Auto Co., Houston, Tex., is planning to erect a new garage, 66x125 feet, on Young street, just off Ervay, at a cost of approximately \$12,000. The building is to be of concrete and one story high.

P. J. Lee, W. T. McKallip and Elmer Abbey, Houston, Tex., have formed a partnership under the firm name of Lee, McKallip & Abbey, and have opened a sales agency for Jackson gasoline and Babcock electric cars.

W. R. Demster, Kansas City, Mo., will shortly open a garage at 1316 Oak street. It is a one story structure specially erected for the purpose, and is exceedingly well lighted. Mr. Demster is looking for a line of cars to handle.

The new concrete block garage of M. F. Case, Cando, N. Dak., has been completed. The structure is 110 feet long by 50 feet wide, and has a cement floor and Ruberoid roof covering. The garage is divided into three sections, the office in front, garage proper in the middle and repair shop in the rear

Sutter & Gamble, of Burlington, Ia., have moved into their new building at 113-115 North Main street. It is a three story and basement structure with a frontage of 40 feet and a depth of 117 feet. The first floor is divided into two departments, one serving as an automobile showroom and the other as a sporting goods selestroom. The second floor contains the automobile repair shop and the third serves for storage. An electric elevator connects the different floors. It is stated that the building will easily accommodate 150 automobiles.

## Trade Personals.

C. H. Hill, formerly with the Cadillac Co., of New York, has severed his connections with that firm, and is now with the Haynes Automobile Co. A. S. Jones, formerly connected with the Philadelphia Ford agency, has been appointed sales manager of the Maxwell branch in Philadelphia.

Henry H. Hower, former auto editor of the Cleveland Plain Dealer, has accepted the position of sales manager for the F. B. Stearns Co., Cleveland, Ohio.

John C. Zimmerman, who was formerly connected with the Fisk Rubber Company for several years, has been appointed Chicago city salesman for the Michelin Tire Co.

James Couzens, secretary and treasurer of the Ford Motor Co., Detroit, Mich., will leave for Europe toward the end of this month to look after the company's foreign business.

H. G. Hamilton, president of the Rapid Motor Vehicle Company, of Pontiac, Mich., has purchased an interest in the Cartercar Co., and has been elected treasurer of the company.

C. E. Davis, superintendent of the American Locomotive Co.'s automobile plant at Providence, R. I., has resigned his position to become superintendent of the Warner Gear Co., Muncie, Ind.

Charles Van Horn, formerly sales manager of the Jackson Automobile Co., Jackson, Mich., has resigned to accept the sales managership of the Selden Motor Vehicle Co., Rochester, N. Y.

Ernest L. Smith, who formerly represented the Standard Roller Bearing Co., of Philadelphia, in the West, has recently been appointed sales manager of the Grant-Lees Machine Co., Cleveland, Ohio.

W. L. Walls has resigned as manager of the St. Louis Maxwell-Briscoe branch, and has been succeeded by F. R. Tate, who had charge of the Goodrich tire agency in St. Louis during the past seven years.

E. Le Roy Pelletier, advertising manager of the Everitt-Metzger-Flanders Co., has been appointed general advertising manager of the Studebaker Motor Car combination, and last week visited South Bend in connection with his new duties.

# New Incorporations.

Chicago Taxicab Co., Chicago, Ill.—Capital stock decreased from \$2,000,000 to \$500,000.

Gary Motor Car Co., Muskegon, Mich.—Incorporators, Alfred C. Gary, William L. Simonton and James L. Maloney, all of Chicago.

Hart Motor Car Co., Chicago, Ill.—Capital stock, \$10,000. Incorporators, Frederick P. Hart, L. A. Shaeburne and H. F. Spangler.

Uhler Motor Co. of St. Joseph, Jefferson City, Mo.—Capital, \$100,000. Incorporators, F. B. Uhler, H. R. Lewis, R. A. Graham and others.

Nicollet Avenue Automobile Co., Minneapolis, Minn.—Capital. \$10,000. Incorporators, F. A. Fitch, O. S. Fitch, H. W. DeParcq and Theodore Wetmore.

Corbitt Taxicab Company, Nashville, Tenn.— Capital stock, \$180,000. Incorporators, H. R. Boyd, J. J. Freeman, Ben Peeples, W. H. Kyle and S. R. Corbitt.

Auto Safety Specialty Co., Buffalo, N. Y.—Capital stock, \$100,000. Incorporators, M. M. Richardson, J. S. Tucker, Childs B. Fish, L. M. Sider and H. Alsworth.

The American Automobile Co., St. Joseph, Mo.—Capital stock, \$25,000. Incorporators, W. G. Campbell, J. Lustenberger, John F. Garber, W. P. Tracy and E. S. Ashbrook.

The Ohio Motor Line Company, West Mansfield, Ohio. Capital, \$10,000. Incorporators, W. W. St venson, A. J. Alexander, J. McGee, W. A. Bell and E. C. Daily.

Mct or Motor Car Co., Indianapolis, Ind.—Capital stock, \$10,000. Incorporators, Leonard Carter, Chas. P. Henderson, Arthur B. Lathrop and Randsom P. Henderson.

The Imperial Automobile Co., Jackson, Mich.—Capital stock, \$100,000. Incorporators, Bradley M. Delamater, Herbert S. Reynolds, Theo, A. Campbell, Franklin Tiffany, E. W. Barber, W. R. Smith, Winthrop Withington, Warren S. Kessler, Thos. E. Barkworth and Jay Clark.

**NEW YORK, JULY 28, 1909** 

NUMBER 4

# Decreasing Cost Due to Increasing Market.

By F. E. WATTS.

We often hear surprise expressed at the wonderful values offered in some of the recent low priced automobiles, and the question is frequently asked how they can be sold at a profit. This question is generally answered by saying that the reduction in the cost of machine work accounts for the drop in price, and this statement is often made as if it accounted for the entire reduction.

Since many of those who are now engaged in the buying and selling of automobiles have never had occasion to look into the factors which go to make up the cost of a manufactured article it has occurred to the writer that some of them may perhaps be interested in the subject. Hence this article, which is a rough statement of some of the principal factors of the cost of production, which enables us to understand, in a general way, how the reduction in selling price has been brought about, and what further reductions may be looked forward to in view of the forces at present acting on the automobile industry.

The following diagram shows the different factors which go to make up the selling price of an automobile. It is a slight modification of a diagram in a recent book entitled "The Cost of Production."

pu

೭

I. Factory cost.

Selling expense.

and possibly drayage at either or both ends of the route. Storage cost includes the work of handling, when storing and giving out, and of keeping track of parts in stock and when given out. Use includes the waste incident to machining raw material or the waste in assembling certain parts. The net price for scrap may be deducted from this waste.

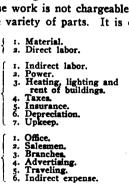

Various methods are used to properly ap-

terial is produced plus the cost for freight.

Various methods are used to properly apportion these charges among the different classes of materials, but many of them are rather rough guesses at the actual facts.

DIRECT LABOR.—Labor is usually classed as direct when it can be entered on the workman's time card so as to be charged against some particular article or class of articles. It is usually taken as including the mechanics who make, assemble, test or finish the different parts. In addition to these a part of the work of the drafting and clerical force is often counted as direct

INDIRECT LABOR.—This is usually considered as including the work of foremen and of part of the office, designing and drafting forces, and in general the work of all people whose work is not chargeable to a considerable variety of parts. It is difficult to

Taking up the final items in order we will first consider the material. This may be roughly divided into two classes, viz., raw material and finished material. Examples of the first would be bar steel, tubing, aluminum castings or any of the hundred and one parts on which work is done at the factory. In the second class would come such parts as frames, axles, steering gears or ignition apparatus, when these are bought complete from outside parties all ready to put on the car.

The total cost of any of these materials is the sum of the purchase price, storage and use. The purchase price may be taken as the cost of the factory where the ma-

distribute indirect labor so that each piece shall bear its proper burden.

Power, Heating and Lighting require no explanation.

RENT OF BUILDINGS.—Rent is usually charged to the factory cost if the buildings are hired. But if the buildings are owned a suitable amount for rent and some of the other items may be charged under the head of profit.

Insurance on buildings, equipment, or parts in the process of manufacture is charged under burden. But insurance on finished machines is properly a part of the selling expense.

Depreciation.—This may be due to a va-

riety of causes. There is always the decrease in the value of a factory, and of tools and other appliances due to age and wear. Improvements in buildings, in methods of doing work, and the advent of new inventions often make this depreciation very rapid, especially in a new business. Increase in the value of the site occupied by the factory, or in the cost of labor and building material, may offset a part of this depreciation.

UPKEEP.—Upkeep, like depreciation, is largest in a new industry, for if the factory is kept up as it should be many new devices must be constantly added.

#### SELLING EXPENSE.

Office.—A part of the office force is directly concerned with the sale of cars, and hence forms part of the selling expense.

SALESMEN.—All manufacturers have salesmen who look after sales in a certain territory, keeping in touch with and appointing sub-agents, and sometimes making sales direct where there are no local agents.

SELLING BRANCHES.—Some of the larger manufacturers have branches in the large cities from which the selling for a specified district is carried on. The cost of running these branches is directly chargeable to the selling expense when they form an integral part of the factory organization. When they are separate in everything but name they are really branch agents, and are not included in the selling price.

ADVERTISING.—Advertising is usually considered as chargeable to the selling expense. But another and fairer way to look at it is as partly chargeable to present selling expense and partly an investment, since it creates a reputation for and a public favor toward the product the company is selling from year to year.

Traveling.—Traveling expenses for salesmen and others are often kept separate from other expenses, and the proper portion is applied to the selling expense.

Indirect Expense.—Indirect selling expense may include part of the salaries paid to higher officials, the remainder being considered as coming under indirect labor. It also includes free repairs and many small miscellaneous expenses.

Profit.—Profit must take care of interest and discount and of rent if the buildings are owned. The tangible expression of profit as dividends varies largely with the policy of the management. In any given factory it may be large or small, depending upon whether a proper allowance is made for repairs, depreciation, sinking fund, etc.

Cost keeping is by no means an exact science, and it may be seen by a glance at

the foregoing that while it is comparatively easy to arrive at conclusions as to the total cost of a completed machine, it is a far more difficult matter to determine the cost of each of its parts with a fair degree of accuracy. The more complicated the costs system and the more it goes into detail the closer should the costs obtained correspond to the actual facts. As a large company can afford a more complete system of records than a small one, it can get more accurate costs, and this is one of the advantages of size, for the more accurately the cost of a machine is known the smaller can the margin of profit be safely made in case it is necessary to cut prices to meet competition.

SOME FEATURES OF THE LOW PRICED CARS.

If we glance over the various details of construction of the four cylinder automobiles selling at \$1,500 and under we note that there are no very marked differences between them and many of the machines which sell at much higher prices. The cylinders are often cast together so that all four hores may be finished at the same time. Some of the crank shafts have only two bearings, but this adds to the weight of the forging and to the size of the journals and bushings, so that the only important saving is probably in assembling. Change gears are usually mounted either with the motor or the rear axle, and are very compactly placed. Here, again, we have a slight saving in weight and in the machine work, with a still larger saving in the final assembling. Operating mechanisms have been simplified. which means another saving in the number of small parts which must be adjusted when putting the cars together. The "block" motor itself is cheap to place in the car, for there are very few connections to make. since water pipes, manifolds, etc., are often cast integral with the cylinders.

ADVANTAGES OF MAKING LARGE QUANTITIES.

But the great saving in machining these parts comes not so much from particular points of design as from the fact that they are manufactured in large quantities. Owing to this fact special fixtures of jigs can be made for every operation, and even special machine tools designed for many of the important parts. Although these jigs and tools may be expensive, their cost is divided by several thousand when applied to each piece. So the tool cost for each piece usually amounts to only a few cents, which is a small amount when compared with the saving in the machinist's time.

But this direct saving per piece is only a small part of the total saving. Where the pieces are made fast the same number of foremen and higher officials can superintend their manufacture that are required where a much smaller number of parts are made slowly. This gives a much smaller expense for superintendence per piece. The same is true for all the other classes of indirect labor, to a greater or less extent.

The saving in that class of factory burden chargeable to the buildings and equipment is no less marked. For the faster the parts

are put through the shop the less floor space is required for each part produced in a season.

At the recent tariff hearing Mr. Durant stated that the cost for direct labor on a car selling at from \$1.250 to \$1.500 was about 14 per cent. This would give from \$175 to \$210 per car for direct labor. But while this seems almost incredibly low, we have shown above that each dollar saved in direct labor may mean several dollars' saving in the factory cost. So machine shop savings, which seem relatively small, decrease the selling price or increase the profit perceptibly.

This saving also applies to the assemling and painting. If a car goes through the paint shop in a week it is chargeable with only a quarter as much burden for the space it occupies as it would be if it took a month to paint it. And it must be remembered that the space and time occupied in assembling and painting automobiles adds very largely to their cost, for the process is necessarily somewhat slow, and the space each automobile occupies is relatively large.

The quality of material entering into the construction of an automobile plays a considerable figure in the final cost. Steels vary in price from about 31/2 cents to \$1 a pound for some of the special grades. The grades used in various makes of cars may be said to run from the lower figure to about 25 cents a pound. The carbon and vanadium steels used in the cheaper cars run from 31/2 to about 7 cents. As a general rule, the cheaper steels machine faster than the more expensive ones, and since nearly as much of the expensive steels must be used as of the cheaper ones, owing to the necessity for rigidity, the saving in this item is quite marked. In the case of castings the sul stitution of grey and malleable iron for aluminum often means a distinct saving in the material cost, at the expense of a slight increase in weight.

In many cases these savings in the initial cost of material result in slight savings in the cost of handling and storage. But there is not generally the multiplied saving which results from a reduction in the hours required for machining.

In some cases, however, where pressed steel parts may be substituted for cast or forged ones, there may be a saving all along the line of manufacture, so the finished piece may be much cheaper indeed.

# LOW PRICES OF PARIS.

The ruling prices of that class of material which is bought by the automobile manufacturer ready made are very much lower than those of a year or so ago. The recent business depression was largely responsible for this sudden drop. At that time there were many parts makers bidding for each job in sight, and naturally the competition brought the bids very low. Indeed they were so low that the parts makers were obliged to adopt every expedient to prevent losing money on their contracts. As some of them said at the time: "You never know

what you can do till you have to," so many of them made a fair profit. But others were unfortunate enough to sustain a loss, so the prices are a shade higher this year. Indications are that they have even increased a trifle in the past two months; nevertheless at the present time frames, crank shafts, axles, change gears, motors, magnetos, etc., can be bought at prices which seem surprisingly low when one remembers the quotations of a couple of years ago.

#### PRO RATA SELLING COST.

The seiling expense where there are a large number of cars to sell is reduced in much the same way that the factory cost is reduced by quantity manufacture. For, while it may take a somewhat larger and more expensive organization and more advertising space to sell 10,000 cars than 500, the expense per car will not be nearly so large when it is distributed over the season's output.

And right here I believe it will not be out of place to mention a popular fallacy. It is common to point to the large salaries paid to some of the higher officials of the larger companies with a kind of mild horror, the idea being that they are a drain on the profits of the company. No doubt that is true in some cases, but the manager who can bring the various parts of a large business into harmonious relationship, who can keep 3,000 or 4,000 men profitably employed, or the man who can sell what they produce expeditiously and cheaply, usually earns all that he gets "and then some."

It has just been noticed how each dollar saved in the shop results in a multiplied saving in the selling price. In this connection let us not forget another phase of the question, namely, cost of the high priced car. The low priced machine is now for the first time made practical by the opening of a large market and the standardization of design. The more expensive car is limited in its field to those who can afford to pay the price for those niceties of material and finish which mean the height of comfort and durability. A car at \$3,000 and one for \$5.000 may look nearly alike, and may run nearly alike, and yet each may be equally good value. For each may represent the cost to produce, by advanced methods, plus substantially the same margin of profit. Each dollar spent for extra work in adjusting or finishing adds considerably to the selling price, and those who wish the refinements of construction should be willing to pay for them

# FUTURE PROGRESS.

In any new branch of manufacture the margin allowed for profit must be high, for changes of design, inventions and variations in the market cannot be as readily foretold as in older industries. New equipment is frequently required; expensive jigs and tools must be thrown away, and new selling methods adopted to interest new classes of buyers. For this reason capital has always demanded a large margin of

profit when entering the manufacture of automobiles.

While this margin has been somewhat reduced by the large demand for the moderate priced machines, it is doubtful if this demand will continue long enough, so that the present factor of profit can be greatly reduced. For it must be kept large enough to safeguard the money invested.

Material prices are not likely to be much reduced, particularly those for manufactured parts. Motor car designs can, however, be still further simplified, with consequent reduction in factory cost.

Just how much the manufacture of motor cars could be cheapened if, say, 50 per cent. of it were controlled by one organization, is an open question. Undoubtedly material could be bought to somewhat better advantage. There would very likely be a slight saving in direct labor. Both selling expense and profit could be slightly reduced, the latter since the market could be controlled in a measure. In the diagram the selling price may mean either of two things. When the car is sold direct through a factory agent or by a factory branch, which is an integral part of the organization, it shows the price to the user. When it is sold through a local agent or separate branch it shows the price to the agent which, with the usual agent's commission of about 20 per cent., is about 80 per cent. of what the user pays. It is possible that a powerful combination might be able to reduce this commission, though whether it is too large or too small is at present a mooted point

Just how great the advantages of combination would be is, as I have said before, a question. "An institution is the lengthened shadow of a man," and when the shadow gets so long that the man cannot see its details clearly there is nothing gained from increasing its size. When the leader turns his attention from manufacturing to combining, inefficiency is likely to begin in the smaller details of the business.

The writer does not believe that under present conditions the efficiency of manufacturing systems can be maintained with further increase in size. The shop which makes 10,000 automobiles a year can probably sell its product practically as cheap as the shop which makes 50,000 in the same time. Theoretically, of course, it can't, but practically I think it can. Let us wait and see.

# Advance in Prices of Crude Rubber.

Consul George H. Pickerell, of Para, furnished statistics showing that in the month of May the export of crude rubber from that port aggregated 2,704,479 kilos, of which 1,168,503 kilos were shipped to the United States. The consul further reports that the prices of crude rubber have increased at a very lively rate. These increased prices are causing each producer to forward to the market every pound of crude he can, and it is believed the effect will be felt upon the coming crop.

# Some Observations on Taxicabs in New York City.

By Joseph A. Anglada.

Considering the abuse to which the average taxicab is subjected, it is surprising that there are not more disabled cabs seen on the streets of the city. That this is the case is not due to the manufacturers, but generally to the intelligent supervision and care taken of the cabs by the operating companies, who, as a rule, have learned that it is cheaper to keep their cabs in a good state of repair than to put off those little repairs which, when neglected, eventually put a car out of commission when it is wanted most.

#### SOURCES OF TROUBLE.

Interviews with men in charge of the repair departments of most of the taxicab garages in the city brought forth the general information that about six months ago the ignition systems gave more trouble than any other part of the car, but that at present the steering mechanism, as a rule, is the weakest part of the cabs, and next to this the gears sets give the most trouble. Some of the cheaper cabs still suffer from rear axle troubles, while on two makes of foreign cabs the motor and the front wheel hubs, respectively, are the most troublesome parts. That there is not more motor trouble is surprising, when it is considered that almost invariably the operator of a cab will race the motor as fast as it will turn when he thinks that it is not operating properly, and this thought seems to occur to some operators quite frequently. The absence of trouble is probably accounted for by the fact that the motors, as a rule, are copiously lubricated and have comparatively short strokes and light reciprocating parts.

Clutches seem to withstand the rigors of the service quite well, because cases of absolute failure are rare, but they require constant attention to prevent them from becoming unduly worn and jerky in engagement. As far as could be learned, there is no preference for either cone or disc clutches, as they both require about the same amount of attention, and in two cases the operating companies stated that the discs of the clutches wore out about every three months, but that this was not objectionable, because the disc clutches in use engaged more progressively than the cone clutches on their other cars and thus strained the transmissions and rear axle shafts less. Breakages of springs are rare occurrences, and tires now give but little trouble, for instead of using 3 inch and 31/2 inch tires, as was formerly the practice with some companies, 4 inch tires are now the rule on front and rear wheels, and in some few cases 41/2 inch tires are used. Quick detachable tires and removable rims are at present finding more favor than the spare wheels to be attached to the rims of deflated tires.

## LUBRICATION.

Most cabs in present use are wasteful of lubricant, because poor provision is made for keeping it where it belongs, with the result that it escapes, generally around the shaft bearings, and into the pan, from whence it drops to the pavement, and causes the unsightly grease spots and rapid deterioration of the asphalt pavement at the cab stands. As a rule no provision is made for lubricating such parts as spring shackles, brake operating mechanisms and the throttle mechanism; or, if provisions are made, they consist of diminutive oil hole covers located in inaccessible places. The provision for introducing lubricant to the universal connections of the propeller shaft, and keeping it there, is also unsatisfactory on most cabs. Transmission cases are in many cases so located that it is impossible to inspect the gears unless the body of the car is removed, and the provision for introducing lubricant to the transmission case and the rear axle housing is not satisfactory to most users, because it is generally necessary to lift the floor boards to get at the gear box, and to get beneath the car to get at the rear axle. It, therefore, seems that if the motor of the cab is fitted with a self contained oiling system. it would be a good idea to connect a copper tube from a screw closed fitting on the outside of the frame to the transmission case, so that oil or grease might be introduced with little trouble, Likewise, if the propeller shaft has but one universal joint, the housing surrounding it should be so arranged that some of the lubricant introduced to it will pass through the tube enclosing the propeller shaft into the rear axle housing. Flexible metal tubes suitable for connecting such parts as the universal joint housing and the clutch shifting collar are at present available, and the writer, therefore, suggests that these parts should be connected by oil tubes to the frame the same as suggested above for the transmission case. The rear axle housing may be lubricated by the same method, or if the propeller shaft has two universal joints the tube may be secured to the torque rod, and a loop of the tube arranged in line with the point where the torque rod is attached to the frame, so that the tube will flex with the movement of the axle. It will, of course, be possible to connect these oil leads to a regular force feed lubricator, also feeding to and driven by the motor, but this is hardly advisable because of the initial cost of the lubricator and the subsequent cost of the oil, a good grade of machine oil being just as satisfactory for transmission parts as gas engine oil, and less costly. The arrangement of the tubes on the frame can be worked out in numerous ways, but the writer suggests that each tube should be connected separately so that when the lubricant is introduced by means of an oil or grease gun it will be sure to go where intended, instead of all going to one or two of the places where the connections are the shortest.

Some of the operating companies have

added or put improved means for introducing lubricant to the front hubs on their cars, because where a number of cars must be cared for diminutive oil holes or the necessity for removing hub caps for the purpose of lubricating the wheel bearings is out of the question by reason of the time required.

# DETAILS OF EQUIPMENT.

In the majority of cases magneto ignition is employed, and almost invariably in these cases the time of the spark is fixed. Taximeters, as a rule, are driven from the front wheels, and in cases where they are driven from the rear wheels the drive will be changed to the front wheels in accordance with the law. On most taxicabs in New York city the operator's seat is located on the right, and the cabs of recent date have a space adjacent to this seat for carrying bulky baggage. The cabs with the operator's seat on the left form a small percentage of the total number, and judging from the operator's viewpoint the left hand arrangement possesses no advantage; but where the change speed and control levers can be arranged on the gear case, as is done on one make of cab coming into prominent use, there is an advantage from the manufacturers' viewpoint, because it simplifies the connections to the gear shaft parts and the hand brake rigging.

The brakes on most American taxicabs are better and easier adjusted than those on foreign machines, and, judging from the opinions of users, are satisfactory as far as holding power is concerned, but unsatisfactory in respect to evenness of braking power and equalization. That is, for an equal pressure on the pedal or lever the effect is not always the same, and usually one wheel is braked more than the other, and principally for this reason it is unsafe to operate most taxicabs on a wet day without tire chains or other anti-skidding devices.

# PROTECTING EXPOSED PARTS.

The location of the tail lamp in daylight, while apparently an unimportant matter, is really important, because two of the large companies have found it expedient to carry the lamp on a bracket at the side of the operator's seat because of the number of lamps which were damaged by passing vehicles and collisions when carried in the customary place at the rear. Likewise, other operators have had heavier bars placed between the front spring hangers to act as a protection for the radiator, and the wisdom of this is shown by the number of cabs seen with this bar bent as the result of a collision, sometimes the fault of the driver, and in other cases caused by truck drivers, who as a class seem to be prejudiced against taxicabs, and have a habit of stopping suddenly when being followed by or when passing a taxicab, in the hope that the cab will collide with their truck.

## COURTEOUS DRIVERS.

As in railway and other systems where a number of men are employed who constantly come in touch with the public, these men are in a large measure responsible for the creation of the feeling of the patrons toward the company. For this reason some of the operating companies enjoy the patronage of that part of the public who are in the habit of using taxicabs regularly, while the other companies receive the patronage of the less discriminating and others to whom the use of a taxicab is still a novelty. In defense of the taxicab operator it must be said that he is subject to complaint and abuse upon the least provocation, and the greater his patience and courtesy, even when unjustly attacked, the greater does he deserve the confidence placed in him by his employers.

The taxicabs of some of the companies present an unnecessarily dirty appearance which does not pass unnoticed by patrons, and certainly does not serve to increase the popularity of the cabs.

#### SUPERVISION OVER DRIVERS.

A method whereby the careful operators may be determined by the company is in use by some, and consists of a record of the daily mileage of each cab, the amount of fuel and lubricant furnished and the extent and nature of troubles or damage sustained by the cab, including the tires. This information when compiled in weekly and monthly statements and compared with the earnings and distance traveled by the cab, in addition to the manner in which the driver has conducted himself, as evidenced by the lack of complaints from the company's inspectors or patrons, gives a correct basis for comparison with the records of other drivers of similar cars under the same conditions. The latter comparison is easily made, because generally there are two or more similar cabs operating from the same stand. Drivers, as a rule, do not object to this mild form of surveillance and those who do are not suitable men to employ. Some companies have made the mistake of not giving a driver the same cab each day, if possible. This practice served to make the driver careless. as he knew that he would probably have another cab the following day, and it therefore did not make any difference to him if he abused the car, provided he did not actually break any part of it. In case a driver knows that he will have the same cab each day, provided it is in good running condition, he will be induced to take care of his charge, for if he doesn't the chances are that he will lose his job, or at least be censured; and, besides, if a man drives the same cab each day he soon learns to know its characteristics and therefore will be able to drive it with more credit to himself and his employers.

For next year's Prince Henry Tour a route is being proposed, starting in Munich and leading by way of Tyrol to Italy and back through Hungary to Berlin. The vice president of the Hungarian Automobile Club recently made a scouting tour over part of the proposed route.

# Book Reviews.

Gear Cutting Machinery, by Ralph E. Flanders. Published by John Wiley & Sons, New York. Price \$3.

This is a carefully written and well illustrated work on the subject of which it treats. The author divides gear cutting machines into classes, first according to the form of gear to be cut, next according to the principle of action involved, next according to the method of operation employed, and then according to the kind of mechanism used, and, following out this classification, all the important machines now on the market, both here and in Europe, are described. The first chapter describes the different methods of forming the teeth of gears, and in the second chapter the description of gear cutting machinery is begun, starting with machines for cutting spur gears. The book contains more than 200 illustrations, of which more than one-half are of complete gear cutting machines and the rest line cuts, mainly of parts.

The Motor Car—A Practical Manual for the Use of Students and Motor Car Owners, by Robert W. A. Brewer. Published by D. Van Nostrand & Co., 23 Murray street, New York. Price \$2.

The author states in his preface that the information contained in the book was first embodied in a series of lectures which he delivered at the Crystal Palace School of Practical Engineering, the Royal United Service Institution, and the Royal Automobile Club. The first eighty-four pages of the work relate to the history and principles of operation of the gas engine, and we are inclined to think that the reader who is looking for information on the motor car will be rather disappointed by this part of the book. The author's excuse for including all this extraneous matter is that the action of the larger and cruder gas engine is easier to grasp than that of gasoline engines. The treatment of the parts of the motor car in the succeeding chapters is of a rather elementary character. The functions of the different elements are discussed and points that must be kept in view in their design are enumerated. most elaborate treatment is given the subject of carburetors and fuels, in which field the author has made experiments.

## How to Remove Carbon.

F. R. Fageol, Rambler representative at Oakland, Cal., recommends the following method of cleaning cylinder walls of carbon: Procure a common housekeeper's metallic wash rag, made of a series of wire rings interlocking with one another. The kind preferred is that in which the rings are composed of two coils of wire, one coil overlapping the joint. Another kind, not so good, is that which has no wire overlapping the joint, and can, with little effort, be pulled apart. One of these metallic articles dropped into a cylinder and the other three cylinders made to run about ten minutes completely removes the carbon,

# Annual Changes in Models.

Of late the practice of designating succeeding models by the year for which they are brought out has come in for considerable criticism. Some makers state that they do not wait till the end of the season to apply an improvement to their cars, but introduce it in their product as soon as it occurs to them. These manufacturers generally refer to their latest lot of cars as "the new series," but this designation, while it may be quite as convenient from the salesman's standpoint, becomes meaningless at a later date. Let us assume that an owner wishes to dispose of his machine after several years' use. The prospective purchaser naturally wants to know its age. To give this correctly is a relatively simple matter for the original owner, but after a car has changed hands several times there is considerable chance of the age of the machine becoming obscured in the mind of the owner and misrepresented to the prospective purchaser. The designation of models by the year would tend to obviate this, and therefore has at least one ad-

Those who argue against the use of the

terms "1000 model," "1010 model," etc., assume, of course, that this practice has some detrimental effect on the industry. It is believed by many that it is responsible for the fluctuations in the demand for automobiles with the seasons, which is one of the greatest handicaps under which the automobile industry labors. That there is some foundation for this argument cannot be denied. A purchaser familiar with the practice of the industry, of bringing out new models with more or less important changes in the fall of the year, is not very likely to buy a car during the summer months, as it would be superseded in a very short time, and would then materially depreciate in selling value. This year, fortunately, we are not likely to have any prolonged dead season, for the reason that many manufacturers have been behind in deliveries, and as they had their new models completed early they could begin work on these as soon as the old cars were off their hands.

But whatever influence the practice of changing models annually may have had on prolonging the dead season, it is bound to decrease as time goes on. The changes in design between successive models are becoming less important every year. Moreover, the public is becoming aware that automobile design is becoming settled, and that a car is by no means obsolete as soon as its manufacturer announces a new model. As long as the automobile is chiefly a pleasure vehicle, sales are bound to fluctuate with the seasons. Also changes must be introduced at some time, and it is certainly not desirable to change models oftener than once a year. One other factor which favors the annual changes is the custom of making annual contracts with dealers. In the fall of the year new agents are always appointed, who are required to contract for a certain number of cars for delivery during the coming season. The dealer, before he signs such a contract, wants to know what kind of car he is to receive, and the manufacturer, therefore, must have his plans for the year complete before he can appoint agents.

The public expectation of new models annually is perhaps particularly irritating to manufacturers whose cars are so satisfactory that there is no obvious chance for improvement. The manufacturer who offers practically the same model year after year runs the risk of being regarded as unprogressive, but upon closer investigation it will generally be found that his car gives

all round satisfaction, whereas if a car is almost wholly redesigned at the end of a year the chances are that it was not very successful.

# Brake Location.

Recent practice favors the placing of both sets of brakes on the rear axle where they act directly on the wheel drums. The reason given for this practice by most manufacturers is that it is desirable to apply the braking force as near the point where the momentum of the car is checked as possible, and since the friction of the tire on the road is used for stopping the vehicle an ideal brake would be one applied at the wheel rim, if it were not for other conditions of operation.

In a sense this argument is true, especially for the heavier braking, for the fewer elements there are between the tire and the brake the fewer there are subjected to heavy stresses and the fewer chances of failure. For there is probably less danger of failure among the connecting rods between the operating lever and the brake than in the parts of the brake itself, since the rods are only stressed by the pull of the operator and the brake parts work against the momentum of the vehicle.

But while this applies to the emergency brakes, which, as their name applies, are often put on suddenly, we are not so certain that it is true of the service brake. This latter brake, being pedal applied, and used in the ordinary operation of the car, can be used much more readily, and hence need not be put on so hard at first as the hand brake. If it is placed on the driving shaft it is well out of the way of the mud and dust, connections are short, and can easily be kept tight, and owing to the fact that the brake is geared up from the wheels a small light brake will do more work than it would on the wheels and can be more easily operated.

The braking effort passes through the differential which equalizes the effect at the rear wheels, and this condition is believed to be desirable for service braking. Finally, though the braking stresses must be transmitted through the propeller shaft, driving gears, differential gears, axle shafts and their fastenings, these stresses, with proper brake design, are no greater than those imposed by the clutch. And if the parts are properly designed with an appropriate factor of safety there is little danger of their breaking. The transmission of braking effort through these parts will no doubt

increase the wear on them, but it was long ago proven that if they are made as they should be they wear a very long time, even with the brake on the propeller shaft.

It seems probable, then, that the service brake will be found perfectly satisfactory in either position, so far as the durability of the mechanism is concerned. And the feature which should decide its location is probably convenience of operation. It is likely that the more perfect equalizing obtained from the transmission brake makes it somewhat the better, particularly for cars of moderate power, where the driving gears and other transmission mechanism may be made amply strong without undue weight.

## Pressed Steel Bodies.

Parts must be standardized so that they can be manufactured in large quantities before they can be made from pressed steel. This is particularly true of large parts, which require large presses for their production and large (and therefore expensive) dies. While pressed steel has been used in bodies for some time past, principally for doors and seat backs, the coming season promises to show considerable development in this direction.

Indeed, we are promised complete bodies of pressed steel. By "complete" we mean to include every part—seats, underbody, foot boards, heel boards, and even the framework to which the upholstery is fastened.

Not only may these bodies be cheaply produced, but they can also be given a very durable finish. By using proper vats they can be dipped in enamel, and though some brush work will doubtless be required, this will be reduced to the minimum. The enamel can then be baked, giving a finish which will probably stand more abuse than the most careful job of painting.

With the appearance of the pressed steel body it will be possible to design a car which is practically all metal, except the upholstery and the ignition wire, for running boards, wheels, dashes and steering wheel rims have all been made from steel. It is of course, an open question whether any other material equals wood for some parts of an automobile, but we can at least view the rising price of lumber with more equanimity if we have a substitute available

Very likely at present prices wood bodies are cheaper than those made from pressed steel, when we compare the unpainted bodies. But it is probable that the enameling can be done so much quicker than a good job of painting that the finished steel body will compare very favorably with its wooden rival, even for cars of moderate price.

# The Speedometer as a Safety Appliance.

Among the many factors entering into safe automobile driving the speedometer occupies a foremost position. This instrument, although it has no automatic mechanical control over the running of the vehicle, does as much in the interest of safety as lights and signaling devices, and possibly even as much as chains and other non-skidding equipment.

High speed is the cause of most accidents, as all will agree. Of course, accidents have happened that were not caused by high speed, but they usually did not result in serious injury. The impact resulting from collisions when going at a high speed is frequently the cause of fatalities. A low speed impact cannot do serious harm. How uncomfortable is the sensation when going at a rate of 35 to 45 miles per hour and the thought suddenly comes to mind "Suppose a wheel should come off or a steering knuckle break!"

Such a speed is always dangerous. We need reminding that 40 miles per hour is unsafe, but in nine cases out of ten, if it were not for the speedometer, the automobile driver would not realize the velocity of his car. Then, again, not only does safety put a limit on speed, but the legal limit should not be exceeded. How is one to tell when these limits are being exceeded? A speedometer, when once installed, becomes an object of constant attention, and although the fluctuation of the needle is dependent on the speed of the car, in a certain and correct sense the speed is controlled by it.

That there is a limit to the safe speed of every automobile must be conceded. This limit, of course, is far above the limit laid down by law. Nevertheless, the fact that there is a limit to the safe speed is most important.

At the present stage of the industry the speedometer, taken together with two or three other safety appliances, must be given high rank as a most influential agent conducive to safe driving and compliance with the law.

# State Dealers' Organizations.

We have now three classes of dealers' organizations, viz., national, State and local. The latest class of organization is the State association, and is represented as yet by only a single body, which was formed at Marshalltown, Ia., a fortnight ago. There is little doubt that dealers in other States will follow the example set in Iowa and join for their mutual protection. One vexed question that a State association is in the best position to solve is that of sales by one agent in the territory of another, a subject that has repeatedly been the cause of litigation.

The objects of the local dealers' associations are generally to co-operate in making propaganda for the automobile locally, by means of shows and competitions, and sometimes to protect themselves against oppressive local regulations. On the other hand, when dealers join in a State or national body, they generally wish to protect themselves in their relations with the manufacturers, though the suppression of "shady" practices in the auto trade may also be one of the objects. The Iowa association, it seems, was formed in order to prevent a recurrence of the annoying delays in delivery which characterized the business this year. Just how the association will go about correcting this evil is not evident. The chief cause for these delays was the unexpectedly large demand for cars which led the manufacturers to accept orders larger than they could fill. Presumably the dealers' association will insist upon a penalty for delay in delivery. The question then would be whether the manufacturers could be forced to agree to such a penalty as long as they can sell more cars than they can produce. Once the demand slackens the delivery problem will solve itself.

Coming Events.

# The Sixth Annual A. A. A. Reliability Tour-III.

BY CHESTER S. RICKER.

Minneapolis to Mankato.

Mankato, Minn., July 19.—Today's rur. was conceded by all the tourists to have been the most pleasant so far. The roads all the way were perfect. They consisted of an alluvial soil which is the finest kind of surface to drive over when it is dry. The drivers, however, began to realize what is in store for them if they have to drive through this when it is wet. A stiff wind blew almost all the time, and as a result the dust was blown away from behind each car almost as soon as it rose, thus making

it a clean and dustless trip for the majority of the contestants.

No troubles of consequence occurred to the contesting cars. Such, however, was not the case with the non-contestants, for the confetti car, No. 97, broke its steering knuckle and was ditched. None of the occupants of the car were injured in the least, although they were considerably shaken up and frightened. The accident occurred about 60 miles out of Minneapolis. The occupants of the car were A. J. May, driver; C. B. Gray, mechanic, and "Mort" Reeves, chief observer.

The run today, besides being the pleasantest, was also the shortest so far. It took the tourists through a rolling country which was dotted with lakes and groups of trees here and there. Mile after mile the tourists ran through fields of waving wheat and corn. The start was marked by the brief but pleasant reception which St. Paul autoists gave us. The first car, Premier No. 1, left at 7:45 a. m. As the cars passed the big Auditorium in St. Paul they were hailed by an officer and made to drive into the building. Once inside the St. Paul autoists treated the tourists to neatly packed boxes of candy, cigars and St. Paul postcards (which, by the way, were already stamped). Around the box was tied a little pencil in the form of a monk, together with the advice to use him and send the cards home.

THE NOON STOP.

Today's noon stop was a great surprise to the contestants. Since leaving Milwaukee the tourists have had to get their lunches wherever they could, but today the Automobile Club of Owatonna had a feast prepared for us. Pretty girls were in charge of the refreshments, and came out to each car to serve its occupants with milk. coffee, lemonade and buttermilk. A neatly done up package containing a couple of club sandwiches and a doughnut was also given to each person.

The route was not without historic interest, as we passed through the town of Northfield, where the notorious James brothers made their last stand. The cars passed around the corner on which stands the bank in which they were caught. Owatonna, in which we stopped for lunch, is one of the largest butter producing centres of the country. Over 3,000,000 pounds of butter were made there during the last year. Pleasant weather, as usual, accompanied the tourists today, and it is promised for tomorrow.

#### TIRE TROUBLES.

At no time before has there been so much tire trouble, which may seem surprising in view of the above statement that the roads were the best and the run was the shortest. The cars suffering from this inconvenience were as follows: Nos. 3, 7, 100, 101, 108 and 114 each had one puncture, while cars Nos. 4, 14 and 105 each had two punctures. Three of the machines which had tire trouble today had the same air in their tires which was put in at Detroit. Cars with clean tire scores up to date are Nos. 2, 6, 9, 10, 51, 52, 53, 102, 103, 104, 107, 109, 110 and 112.

## BRUSH RUNABOUTS WITHDRAW.

The announcement was made tonight that the Brush runabout entries, Nos. 103 and 104, have been withdrawn. The reason given is that the schedule is too fast for these little 7 horse power runabouts. The majority of the drivers of the other cars have been thinking the same for some time. They agree, however, that it will mean far more if they get through going at the speed for which they were designed, rather than fail only because they were driven at an impracticable rate.

#### TODAY'S PENALTIES.

Only two cars received penalties today, one on account of a recurrence of a trouble which began on the first day out. The other defect was a new development, however, and was probably the first noticeable effect of the terrible punishment which the cars stood on the run from Madison to La Crosse. Car No. 3. Chalmers-Detroit. driven by Bolger, lost another point today on account of tightening up the mud guard, which broke loose on the first day of the run, and has been penalized 2.4 points in all to date. The Jewel car, No. 111, driven by Shimp, had to have the bolts in the rear wheel hub flange tightened. For the driver's time 2.3 points were imposed, together with 3.5 points for the mechanic's time. Total points, 5.8.

The Maxwell press car, No. 82, driven by George Illingsworth, which is accompanying the tourists, bent its steering knuckle this afternoon. The manner in which the accident happened was reported as follows: They had turned out to give way to the Pierce runabout, No. 108, driven by Williams. In the long grass which bordered the road the driver was unable to see a deep hole, into which he plunged, the result being that he came out with a bent knuckle.

## ROUTE CHANGED.

The route was changed because the bridge across the Mississippi which we were to cross was closed. As a result the distance was increased about 3 miles, and more than one unfortunate lost the road. Gus Buse, driving the big Thomas entry, No. 11, lost over forty-five minutes and yet finished well within time.

There was almost no racing, as the chairman held to a steady schedule, and was seldom over twenty minutes ahead of time during the day. The roads were so fine that

RAPID TRUCK CARRYING TIRES AND AIR BOTTLES.

WHERE BUSE'S THIMAS SANK INTO QUICESAND

there would have probably been a great deal thing that we will have the Pullmans there, had he not done so.

Beginning at Fort Dodge, we will have the

# LITTLE MISUNDERSTANDING.

There seems to be very little misunderstanding of the rules this year. In a measure this may be due to the small amount of trouble which has happened so far, "When the shoe pinches one usually hollers," and it takes such an impartial judge as Mr. Hower to handle each of these cases. So far no one has questioned any decision the chairman has made.

## DAI LEWIS' ROUTE BOOK.

From the number of schoolhouses which Dai H. Lewis has recorded in the route book it is evident that the younger Americans in this country will not want for an education if they are disposed to get it. The same is equally true of churches and graveyards, for there is probably not one on the landscape which our jovial pilot has not recorded in the route book.

# THE BUNNING TIME TODAY.

Class A-6 hours 36 minutes.

Class B-6 bours 46 minutes.

Class C-6 hours 56 minutes.

Class E-7 hours 16 minutes.

Total mileage 132, with 3 miles additional caused by the detour in St. Paul.

# ENTERTAINMENT AT MANKATO.

A Dutch lunch was served at the Elks from 8 o'clock until as late as was desired. It was given under the auspices of the Mankato Automobile Club, and was very enjoyable, although all the tourists desired to retire early. John H. Holmann, the president of the club, was the host.

The American Simplex agent here tendered a three hour boat ride on the Minnesota River. Those who could go on the trip enjoyed it very much. The fact that a general meeting was called at 8:30 made it impossible for the greater portion of the tourists to take advantage of the occasion.

## RUMORS.

It is reported that the Ringling Brothers Circus will be at Fort Dodge the same day as we are. For this reason it is a fortunate thing that we will have the Pullmans there. Beginning at Fort Dodge, we will have the sleeping cars all the way to Kansas City. The made just out of Fort Dodge and as far as Moorland are reported as bottomless, and so the route has been changed by the local authorities on the advice of Pilot Dai H. Lewis.

# Mankato to Fort Dodge.

Fort Doore, Iowa, July 20.—To-day's stage was, with one exception, the shortest we have had so far. The going, however, was not as good as it was yesterday, and although only 138.6 miles had to be covered it required considerable physical effort on the part of some of the occupants of the cars.

As far as Elmore, 55.1 miles, the tour led over excellent dirt roads, and the tourists expected the same pleasant time they had the previous day. Some of the drivers were aware of the condition of the remaining 84 miles and "opened up wide," notably the Pierce contingent, cars Nos. 8 and 108 both passing us at Blue Earth, 45 miles from Mankato. The Premier No. 1, in which the writer was a passenger, had started at least 15 minutes ahead of these cars and maintained a 22 mile an hour schedule, from which it may be seen that the Pierce cars were traveling at a very good clip. However, although racing was indulged in, it was "method in madness," and not for the joy which it does not give. The drivers have learned that one never can tell how the roads will be later in the day, and so they always take advantage of the good stretches to gain on the schedule. Every one arrived in Fort Dodge sufficiently early to oil the car before checking in, but fast driving over the good stretches enabled them to save their cars on the had stretches.

After leaving Elmore we ran for 25 miles through a swampy country with little ponds and treacherous logs on each side of a narrow road. So narrow and rough was the road that many cars barely escaped

a mud bath in the dangerous pools. Three of the cars in the tour were ditched as a result of the treacherous nature of the ditches.

No. 82, the Maxwell press car, ran out of gasoline, and when pushed to one side to let pass the Marmon car, No. 5, driven by Howard Marmon, it became mired. Marmon was unable to draw the Maxwell back on to the road again, but after the driver of the Maxwell had filled up with gasoline he was able to get back onto the road again under his own power and with the assistance of the passengers pushing.

Snyder, driving the Mason car, No. 112, was another unfortunate. He also turned out for an approaching car and found himself stalled. The Midland, No. 12, driven by Hayes, lent him aid, and finally drew him onto dry land again. The Rapid truck, No. 75, was also ditched, but was rapidly pulled back onto the road by the Studebaker and Thomas press cars, and was then able to continue.

Saturday last there was a cloudburst in this section of the country, and the roads were washed away fearfully, according to reports. The farmers, however, took the matter promptly in hand and dragged the roads for miles. Most of the contestants appreciated the effort that had been made to put the roads in good condition for them. The temperature to-day was the highest so far on the tour. Mr. Glidden told the writer that the record was 115° in the sun and 94° in the shade. A strong head wind made it quite comfortable, however, all day long

# TWO ACCIDENTS.

Two accidents occurred to the non-contestant contingent today. The first was to

the E-M-F confetti car, which was passed in trouble at Vernon Center, 21.1 miles from Mankato. This was the same car which broke a steering knuckle yesterday. Today it broke the rear axle and lost the wheel on the opposite side from the front one which came off vesterday. No one was injured, and the occupants were picked up by one of the big Studebaker cars. The second accident was of a more serious nature. E. L. Ferguson, secretary of the Touring Board, was hurt quite seriously. While traveling at a fair rate of speed his car struck a pool in the road and was ditched alongside of a barbed wire fence. Mr. Ferguson was pitched violently into the westsu

COGAN

AMESOURI VALLEY

HOMEY CREEK

COUNCIL Bluffs

DOMANA

COUNCIL Bluffs

DOMANA

fence and sustained bad lacerations of the body and hands. His hip was also injured. PENALTIES.

Only three cars incurred penalizations today. Car No. 107, the Maxwell runabout, had 1.6 points entered against it, which were held over from several days ago. Car No. 12, the Midland, driven by Hayes, had further trouble with its fender, and was penalized 0.6 point for repairing same. As far as the writer remembers, trouble with fenders and fender irons has never been the case of penalizations in previous tours, but two fender brackets have already broken on this tour.

Car No. 3, the Chalmers-Detroit, driven by Bolger, incurred the heaviest penalties to-day. Its score was not officially, announced tonight, because it did not arive until 5:40 o'clock. It was said that 170 minutes' work was done on the car, which will probably entail 17 points penalty, and for late arrival 187 points will probably be imposed. The lateness was due to trouble with a loose crank pin bearing. Bolger told the writer that the babbitt which had been put in the bearing was in four separate pieces, as though oil had been spilled into the babbitt when poured.

BULLETIN.

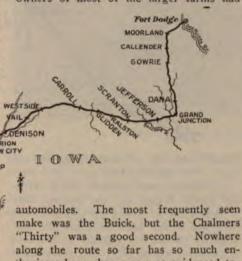

This evening the following "Bulletin" was posted:

"Running time for July 21 will be nine hours forty-eight minutes. The distance is 196 miles. Where confetti does not agree with route book, ignore book and follow confetti. Baggage can be left on the train."

STOPS ON THE ROAD.

During the morning we stopped at Elmore, where buttermilk was served to the tourists as they passed. At Algona, 93.6 miles from the start, we were served beer, and the most delicious ham sandwiches we have had anywhere. The town is "dry," but the boys secured as much beer as they could carry, and after we left there the road was strewn with empty beer bottles for miles.

It was noticed during the day that the owners of most of the larger farms had

make was the Buick, but the Chalmers "Thirty" was a good second. Nowhere along the route so far has so much enthusiasm been shown as was evidenced today. At Fort Dodge, however, Ringling Brothers' Circus completely put us in the shade, there being scarcely anyone to meet us upon our arrival.

The guard at the open air garage where the cars are parked tonight is the most formidable so far. Soldiers in full equipment guard the machines. They carry fixed bayonets and have their tents pitched in the centre of the hollow square formed by the cars.

Ever since we left Madison there have been cases of sickness. Every now and then a car will carry ballast, for a day at least, and sometimes longer, the unfortunate passenger replaced by it going by train

# Fort Dodge to Council Bluffs.

COUNCIL BLUFFS, Ia., July 20.—The run today was the longest so far, and was much

dreaded by the contestants. A cloud burst that occurred about a week ago had washed the roads out in several places, and as a result several detours had to be made. This increased the mileage from 185.5 to 106.

The roads, although they had been reported to be very bad, were really among the best we have had so far. From Paton to Carroll they were almost as smooth as macadam, and since bad roads were anticipated in the second half of the stage the tourists took advantage of the fact and kept up a speed of from 30 to 35 miles per hour. As these good roads continued for over 50 miles, the majority of the cars were soon far ahead of the schedule. Really bad roads were met with at only two or three points, extending only short distances, with the result that almost all the contestants arrived at the night control an hour or more ahead of time. The Pierce cars were the first to finish, and were more than two hours ahead of their schedule.

Several bad mud holes were met with on the road, and one of these was so deep that friendly farmers had put planks over the mud specially for the contestants. Car No. 81, the Studebaker, driven by Harry McIntosh, got into a rut just before reaching the planks. It plunged hub deep into the gumbo, and McIntosh was unable to extricate the car by means of its own power. The railroad, however, parallels the road at this point, running very close to it, and men on a work train nearby hitched a rope on to the car and dragged the Studebaker out of the mud.

Another car mired during the day was the No. 10 Glide, driven by Bartholomew. The car got off the road and sank so deeply into the mud that horses had to be brought to its aid. The unfortunate accident sharply bent the left front steering arm, so that it had to be replaced, and as a result another car lost its perfect score. The Lexington runabout, No. 114, was also mired, but was pulled on to the road again by the Studebaker press car. Car No. 111,

CARS PARKED AT COUNCIL BLUFFS.

the Jewel, driven by Gus Uhl (who was taken Shimp's place), ran into a bank and bent its steering knuckle, and also badly dished its front wheel.

Not since we left Minneapolis have we seen such beautiful country. The last 50 miles led through an exceedingly fertile section. The crops seemed to become heavier and better cared for the nearer we approached to the river. The farm houses and the people in the towns were entirely different from those we saw earlier in the day. If automobiles are an indication of prosperity, all that is necessary to indicate the state of the country is to mention that such cars as the Locomobile. Stoddard-Dayton, Pope-Hartford and Winton were most in evidence along the road, and the Chalmers "Thirty" was also well represented, while in the vicinity of Minneapolis Buicks and Reos were in the lead.

The cause of yesterday's accident to the secretary's Acme car was given as a loose coupling on the tie rod between the front wheels. A new joint had been put in at Detroit. It was said that the pivot bolt was not tightened at that time, and so the rod worked loose, and finally permitted the two steering wheels to become separated.

Complaints of speedometer trouble are beginning to be frequently heard now. Very few of the cars are equipped with more than one instrument, and where only a single one is carried it is extremely aggravating to have it suspend operations. Car No. 1, on which the writer is a passenger, is equipped with two instruments, a Warner and a Stewart, and both are still in perfect working condition. It is next to impossible, however, to keep the gears in mesh continually, and until the day before yesterday we had only one operating most of the time. Dai H. Lewis says that on the prairie it is almost impossible to tell where to turn, unless one has an accurate instrument to go by, in addition to the route book.

More perfect records were broken in today's run than ever before, the following cars losing their perfect scores: Nos. 4. 7, 10, 53, 100 and 102. The only car that did not report on time this evening was the Chalmers, No. 3. It had further trouble with the bearing which began to give

was in the gears. No. 102 lost 30.3 points for replacing a taper pin in the hub of the gear which drives the timer shaft, the pin having sheared off.

trouble yesterday. A new bearing was put in, as has been reported.

The perfect score Marmon, No. 4, driven by Frank Wing, and the perfect score Premier, No. 53, driven by Cliff Waltman, both had trouble with leaky gasoline connections. No. 4 lost 8 points for the time required to fix the leaky connection, while No. 53 only lost 0.8 point for the same

The Jewel touring car, No. 7, driven by Bernhardt, also lost points. Sixteen points were assessed against it for two rear hub flange bolts which were bought, and for the time taken to put same in place.

Another perfect score was spoiled when the Glide car, No, to, had to replace a steering knuckle on the left front wheel. The reason was stated earlier in this report. A penalty of 1.6 points was imposed for time, and the cost penalty was held until later.

Two of the up-to-now perfect score Molines met their "Waterloo" today. No. 100 lost 3.1 points. This was caused by a steel chip getting into the timing gears. On examination the driver, C. H. Vandervoort, found that it was not necessary to remove the chip, but it relieved the minds of those in charge of the car to know nothing worse Car No. 111, the Jewel, now driven by Gus Uhl, lost 8.4 points because it required tightening of the spring clips and tire holders. The rear wheel was removed, so it was reported, to tighten up the hub bolts which were loose. Further penalization accrued from having to straighten a front knuckle, which was bent in the sand bank.

SMALL CARS.

All the little cars, that is the Hupmobile, No. 106, and the two Brushes, Nos. 103 and 104, arrived on time today. They are non-contestants, of course, but they made a good showing.

The White steamer, No. 14, driven by H. N. Searles, has been giving a remarkable demonstration of how a car can be run on kerosene. It has been running unostentatiously, and has no history.

PULLMANS.

Last night the whole party dined on the cars, where they also slept. General satisfaction was expressed at the service, especially the dining car service, and the party acknowledged that no such service had been had since leaving New York or Detroit.

The sleeping cars were not so satisfactory, as it was a draw for the upper or lower berth, and the uppers were not in demand. Another complaint is that there is no place to wash up when the tourists arrive, as they usually beat the train into town.

Up to now the tourists have covered 1,289 miles, and they still have 1,458 to go. The cars having tire trouble the last two days are as follows:

July 19—Cars Nos. 3, 4, 7, 14, 100, 101, 105, 108 and 114.

July 20—Cars Nos. 1, 6, 7, 10 and 14. July 21—Cars Nos. 51 and 105, the least of any day so far.

THE NIGHT'S MEETING.

The meeting was conducted by Dai H. Lewis, and was quite brief. He particularly cautioned the men against throwing matches on the sides of the roads. He also advised observers to take the time of the approach and departure from washouts. And to always get a bill of sale when parts are purchased on the road.

# Council Bluffs to Kearney.

Kearney, Neb., July 22.—So far we have had no rain whatsoever, and the tourists are very grateful to "Jupiter Pluvius." The roads were perfect almost all the way, and very dusty, as there has been no rain for about ten days hereabouts. Nevertheless one mud hole was met which held the big

LEXINGTON, DRIVEN BY JOHN C. MOORE, ON LOUP RIVER BRIDGE.

Thomas No. 11 in its grasp for about forty minutes. Several smaller ones were also encountered, but no one else was mired. The stretch of road which parallels the Union Pacific tracks for the last 20 miles was the longest consecutive stretch of smooth road which we have thus far found. Several cars met the Overland Limited at this point, and one of the press cars is reported to have easily passed it. This shows that the road surface was excellent. Kearney probably has more cars in proportion to population than any other city of its size in the United States, viz.: one car for every forty-five inhabitants, I was told.

This run was the most tiring of any which we have had so far. The distance was 200 miles, and the ride proved exceedingly monotonous owing to the level and unchanging nature of the landscape. Here and there we passed a grove of trees, but except for these there was nothing to break the view to the distant horizon. The heat, which was not unpleasant when the cars were in motion, was unbearable the moment they stopped. So severe was it that even those who had a heavy tan are tonight nursing their blisters. E. L. Ferguson, secretary of the contest board, who was badly cut the other day when he was thrown into a barbed wire fence, has not improved. His hand is frightfully blistered and swollen, and his condition is so serious that it was thought advisable to have him go on ahead to a hospital in Denver.

# ANOTHER CAR OUT.

Another car was dropped today. The Chalmers-Detroit No. 3, which had bearing trouble Tuesday, was withdrawn, and will continue from now on as a non-contestant. The bearing had to be replaced, as was expected after it had been inspected on the day when the trouble first occurred. Much regret is expressed that the only Chalmers in the contest for the Glidden Trophy should be withdrawn.

## PENALIZATIONS.

Only two other cars besides the Chalmers received penalties as a result of the day's run. Two other penalties were changed, however. The only car with a perfect score now competing for the Detroit Trophy is the American Simplex No. 51, driven by W. A. Wood. This is the only two cycle

BRUSH RUNABOUT ENTERING KEARNEY, NEB.

ble, and before it could be repaired 6 points had been charged against him.

The Jewel roadster had to replace a spark plug during the day, and since this is not a part which is carried loose, the square parts bag had to be opened, and a penalty of one point was incurred. The time necessary to put the plug in place added another .4 point, making together 1.4 points, and with former penalties this makes a total penalization of 30.3 points.

The scores changed were on the Glide No. 10 and the Moline No. 102. The former had one point added for the cost of the part replaced. This had not been determined yesterday when the report was given out. The Moline car was penalized 30.3 points yesterday, but on account of some mistake in calculating the work penalty the actual penalty is changed to 16.1 points.

## RUNNING TIME.

The running time was set at exactly ten hours for the Class A cars. The strange part of the schedule was that practically every car exceeded it during the day, and almost in every case without intention. The reason for this was that, except for the first few miles, in the immediate vicinity of Omaha, the roads were as level as a billiard table.

## TIRE TROUBLES.

The long distances, speed and high temperatures are beginning to have their effects on the tires, and tire trouble is inwas of the opinion that he had probably lost his clean score.

#### MECHANICAL TROUBLES.

A number of mechanical troubles that are not officially penalized have become evident. The continuous strain which the cars are subjected to is certainly making itself felt. Several cars have lost their fan belts and long steady plugging across the level country on these fearfully hot days has caused the motor to heat up considerably. These telts cannot be replaced without penalty, and so they are not replaced. One case is known where the valve stems stuck. Some of the valves have evidently begun to warp and it will be interesting to note the way the cars will act after they have run 1.200 miles further. Several steering gears have a large amount of lost motion and in one case the trouble is so pronounced that it seems foolhardy for the driver to continue without doing something to rectify the trouble. Wheels have also suffered. One or two are dished, and one, to my knowledge, has very loose spokes. Most of the contestants are using an excess of oil in their motors, with the result that carbon deposits have formed in the cylinders and preignition is giving some trouble. One car had a very extraordinary break. The steering column tube broke just back of the dashboard, but fortunately no harm was done to the steering column proper.

## THOMAS STUCK IN MUD.

About 95 miles out of Council Bluffs the Thomas No. 11, driven by Gus Buse, was mired. The Rapid truck, which was the first car to arrive, failed to budge the big car. Neither could our car, Premier No. 1, when acting in conjunction with the truck. Even with the additional aid of the Jewel No. 7, the car could not be moved. Finally some one suggested the use of a block and tackle which almost every car on the tour now carries. One block was put on the Rapid truck and the other on the Thomas, then the loose end of the rope was attached to the Premier, and when the latter was started up it soon had the Thomas out.

# EFFECT OF THE HEAT.

Yesterday was so hot that the chairman was nearly prostrated. Several of the

car in the tour, and the consistent performance which it has made so far has been the cause of much favorable comment on the part of other contestants. No. 52, Chalmers, driven by Jean Bemb, also met with a mishap entailing penalization. Bemb's commutator shaft gave some trou-

creasing. Today's run saw the following cars delayed by punctures, etc.: Nos 2, 3, 7, 11, 14, 101, 105, 108 and 114. The White No. 14, driven by H. N. Searles, had no less than five punctures or blowouts and was delayed thereby 180 minutes. Searles got in so late that almost every one

drivers and passengers also felt the heat very badly, and in consequence Mr. Hower, for the first time in any Glidden Tour did not go by road. Instead he remained on the train, and probably had a much pleasanter trip than we unfortunates on the cars. During the day we were passed by the train twice, and Mr. Hower, from his observation car, was able to keep an eye on the run. As today was still hotter it was surprising that no worse experiences were noted.

#### LUNCHES.

In this part of the country it is not always possible to get a good lunch on the road, and so the Pullman dining car served us each morning with a tastily prepared lunch, put up in a card box. Last night the Council Bluffs Auto Club certainly outdid themselves in order to entertain the tourists. They arranged with the Elks to take care of us upon our arrival. As most of these cities are "dry," the B. P. O. E. rooms were put at our disposal. After the cars had all arrived, special trolley cars took the tourists to a lake, where they had a delightful swim. At 8:30 a banquet was served at the Grand Hotel to all who desired to go.

Little baggage is now being carried by the tourists, as almost every one leaves his

C O L

baggage in the Pullmans which go from night stop to night stop. Before this it was very uncomfortable to travel in the contesting cars as they were so heavily loaded that there was little leg room.

# Kearney to Julesburg.

JULESBURG, Col., July 23.—To drive 200 miles in the broiling sun over a prairie, absolutely devoid of anything to break the monotony, is not a particularly pleasurable experience. From remarks overheard in the early part of the tour, it was evident that not a few of the tourists thought the tour would be a "joy ride," but they have since found out that they were sadly mistaken.

This morning dawned clear again, and the roads for the first 100 miles were not very bad, although rough in places. The last 100 miles, from North Platte to Julesburg, was without doubt the most trying stretch so far, excepting the fourth day's route from Madison to La Crosse. The roads for this latter 100 miles' stretch were across the range and were nothing less than two or four ruts in the prairie grass. At frequent intervals these were intersected with culverts, holes, sand or deep gullies. The sand which was met with in several places tried the cars more severely than

hills which have been encountered. of the sand hills proved too much for

five of the cars, and horses were required to extricate the machines. The ranchers probably anticipated trouble, for they congregated in numbers to watch the cars get stuck. The charge made was a dollar for each car.

As a variation from the routes of previous days the population along the road was very scarce, and we repeatedly drove 15 to 20 miles without seeing a single habitation. The railroad was the only sign of civilization in sight. Some of the grades encountered, although short, were very steep. They were miniature cañons, and their sharpness and the crookedness of the road leading through them taxed the drivers' ability in negotiating them. In many cases the bottom was of sand, the kind of sand which is so dry and light that it flows almost like water, and the cars plunged about like so many ships.

The people along the way did not seem interested in the tour to the same extent

as those in the more densely populated districts passed through earlier. The horses on the route were not so familiar with cars as they are further east. Several runaways were reported, but none serious. Some dogs along the line met their fate also. Most of the animals do not appreciate the speed at which an automobile can travel, and find out to their misfortune.

## RUNNING TIME.

A rate of 20 miles an hour was demanded for Class A cars. This means that the 206 miles had to be covered in 10 hours and 19 minutes. Little difficulty was met in maintaining the requisite speed over such long distances. The car in which the writer rode, viz., the Premier, No. 1, stopped for an hour to clean a carburetor, and yet checked in fifteen minutes ahead of the time limit. Several stops had also been made to oil up the car. as is the prevailing custom among contestants.

# PENALTIES.

There was apparently very little mechanical trouble on the road today. The only cars which were penalized were the Glide, No. 10, Moline, No. 102, and Jewel, No. 7. The Glide found it necessary to replace a front spring. The car was penalized 4.2 points for the spring, and 5 points for the time required to make the replacement, making the total penalty 9.2 points. O. P. Bernhardt, driving the Jewel car, No. 7, met with a piece of bad luck that led to his penalization. In the little town of Ogallala, 169 miles out, he ran into a little Ford runabout. The Ford was driven by the owner

for the first time. The latter lost his head, jumped from the car and allowed it to run on. Bernhardt, having the choice of running down a telegraph pole or into the Ford, chose the latter. His mudguard was badly bent, while the Ford was completely disabled. Before starting the mechanic pulled the fender up, and as a result was penalized for a minute's time, or or point.

The Moline, No. 102, lost a loose fender bolt, and for buying a new bolt and replacing it the car was penalized 0.2 point for the cost of the bolt, and 0.8 point for labor, together only 1 point.

Tire troubles were very general today, but of mechanical trouble there was less than on any previous day of the tour. Considering the condition of the roads, and the speed at which the cars are driven, this is remarkable.

SOME MECHANICAL ASPECTS OF THE TOUR.

The cars are undoubtedly overdriven, and the pounding they have to stand in consequence is making itself evident, but the way the cars stand it is marvelous. The opinion of all is that there was not a car built twelve months ago that could have stood the pounding so far. The ruts, which have been a menace to the drivers for the last two days, give the cars a racking which no other roads could possibly do. The cars travel at a speed of anywhere from 25 to 35 miles per hour, and when they slip into the ruts a severe lateral thrust is imposed on the wheels that is unknown on Eastern roads. The ruts vary from two or three inches to a foot in depth. Further, the tracks lead in a course like a snake's path, and it is almost impossible to follow them. The steering gears also receive very severe punishment.

## AT KEARNEY.

The citizens of Kearney who are organized in an auto club gave us a delightful time in so far as they had facilities. On arriving the tourists were given printed breast ribbons, which admitted them to all festivities held there that night In the afternoon they provided baths for us, which was a welcome treat. At the hotel there was plenty to refresh the inner man, and much of a nature which is really not permitted in this "dry" country. In the evening they gave a banquet to the Gliddenites, which was so attractive that many were sorry the next morning that they had stayed up so late the night before, with a 200 mile drive before them. In almost every town or city passed through we have been treated most cordially. In some cases the provisions for our entertainment made really too great demands on our time. The drives this year are longer and harder than ever before, and few of the tourists are able to retire before 10 or 11 o'clock, and all have to turn out before 5 in the morning.

Julesburg to Denver.

Denver, Col., July 24.—Watches are now set one hour back, or on Western time, and as a result everyone was able to get an (Continued on page 107.)

# NEW VEHICLES

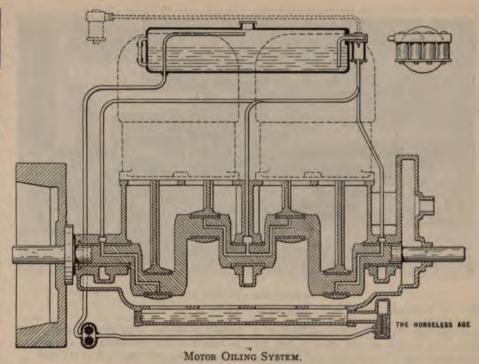

# The Petrel Four Cylinder Cars.

These machines are made by the Petrel Motor Car Company, of Milwaukee. The name Petrel was given them on account of their alleged unusual ability to make good speed over very rough roads. They are especially designed for the class of work required of motor cars in our Western country.

Two models are made, a touring car and a roadster. In general plan they are exactly alike, but their wheel bases and arrangement of parts are somewhat different.

The bore of the motor is 41% inches and its stroke is 41% inches. The cylinders are cast in pairs, with valves all on one side. The crank shaft is of 0.35 per cent. carbon steel and the connecting rods are drop forged. All working parts are carefully ground. All journals, except the piston pins, are bushed with white brass. The pin bearings are of hardened steel, carefully fitted. The crank case is of aluminum, split horizontally.

As shown by the figure, an oil tank is provided in the base of the motor. Oil flows through filtering screens to a gear pump, which forces it to an elevated tank. From the tank it flows by gravity to the main bearings, passing through the holes drilled in the crank shaft to the crank pin

bearings. Ignition is by the Atwater Kent Unisparker. Cooling is by water, with gear pump.

Power is transmitted through a universal coupling to a friction speed changing device and thence by side chains to the rear wheels. The change speed device is known as the "Waite friction drive," It is the typical disc and traversing wheel, and

differs from others of its kind chiefly in operating means and detail design. Contact is made by a compression spring whose pressure is adjustable. This is set to give pressure enough to a little more than drive the car under ordinary road conditions. Pressing forward a "clutch" pedal releases this contact. For transmitting an unusual amount of power, as in heavy going or while climbing hills, another pedal is used which forces the disc directly against the wheel through a linkage. The position of the sliding wheel is regulated by means of a hand lever.

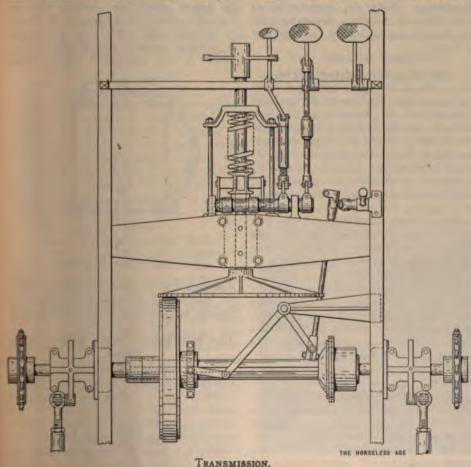

The frame is a typical pressed steel construction. The front axles are tubular. Special attention has been paid to the spring suspension, a good many combinations having been tried out before the present set of four semi-elliptics was adopted. The tires are 32 by 3½ inch on both models. The gasoline capacity for the touring car is 15 gallons and that for the runabout 20 gallons. The runabout has a wheel base of 108 inches, while that of the touring car is 115 inches.

The standard colors are English violet for the runabout and violet purple for the touring car, black and gold striping being used on both models. U & H magnetos are fitted at an extra cost.

# The Avery Farm and City Tractor.

The Avery Company, of Peoria, Ill., has recently added to its line of farm machinery a farm and city tractor designed by J. B. Bartholomew, its president. This new machine is the result of two years and a half of study and experiment. One of the tractors has been completed and is undergoing tests in various lines of work for which it is adapted.

The tractor has a four cylinder gasoline motor mounted in front. The chassis will

THE AVERY FARM AND CITY TRACTOR.

accommodate either a truck platform or a tight box, a rack or any form of bed for carrying loads. It will also pull three or four 14 inch plows, pull a drag or scraper for smoothing public roads and haul loads on ordinary farm wagons and other vehicles behind it.

The motor shaft extending in front is to be provided with a suitable pulley and can be used to shell corn, run a small individual farmer's thresher with 22 inch cylinder and 36 inch rear, including all the attachments; pump water, saw wood, bale hay and do various other jobs that need to be done on the average farm.

The wheels of the tractor are fitted with a steel rim perforated and studded with 2 inch hard wood plugs, which are claimed to enable it to run smoothly and silently on paved streets. It is claimed that these plugs will wear for a great many years and can be renewed at very slight expense. The manufacturers state that these wheels will not damage the paved streets, so the tractor can be used for all kinds of hauling and trucking for city use, as its hauling capacity is three tons on its own wheels, in addition to the weight of the tractor, which is 4,600 pounds. The speed of the machine on the public highways is 10 to 12 miles per hour, and the tractor is said to be capable of climbing the steepest grades with its load.

# New Veeder Motorcycle Trip Cyclometer.

The Veeder Manufacturing Company, of Hartford, Conn., have recently placed on the market a type of cyclometer which is especially adapted for motorcycles. Small attachments used on motorcycles are subjected to very hard usage, and it is with this knowledge that the new motorcycle trip cyclometer has been constructed.

The case is increased in size, the gearing is heavier, and it is equipped with a larger star-wheel than regularly used on a bicycle cyclometer, and the large motorcycle striker with the adjustable bracket which is regularly supplied makes it altogether a most durable instrument, it is claimed.

The adjustable bracket is a feature which deserves special mention. This bracket can, by simply loosening one nut, be made to fit any American or foreign motorcycle. This can be readily appreciated by the dealer, who before has been obliged to stock with special attaching fixtures for various makes of motorcycles.

The mile figures are in white with black background, the tenths of miles in red, black background. With this combination of color the rider can easily distinguish from the seat the reading of his cyclometer at all times.

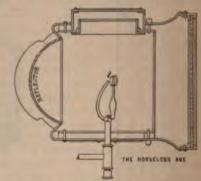

## The Wunder Button Light,

As a result of experiments begun about three years ago, the Wunder Button Light Company, of 242 Lafayette street, New York city, has developed and just placed on the market a fixture to replace the usual fan shaped flame burner used in automobile acetylene headlights. It consists of a burner producing an intensely hot pencil flame, which is directed against a button consisting of a material the composition of which is withheld by the manufacturers. The button becomes incandescent on the side against which the flame is directed, and the light striking the mirror of the lamp is reflected in the usual way.

The color of the light produced is whiter than that of the ordinary acetylene burner flame, and the spectrum of the light shows that the percentage of blue and green rays is greater than in an acetylene flame. The makers claim that about one-half the quantity of gas used by an ordinary burner is sufficient to produce a light of the same candle power, but of greater penetrating power, because of the small loss by sidewise light radiation and also by the elimination of the heat radiation inseparable from a luminous flame, due to the blue flame produced by the burner, which radiates but

little heat. The flame may be reduced or turned down and operated so that very little light is produced and may be instantly increased to full brilliancy without the disposition of carbon in the burner. It is necessary, however, to provide the gas under a pressure of about 2 pounds per square inch, making it necessary to alter the gas generator for this pressure or to use a gas tank. In the event of too much gas being fed to the burner the flame will be extinguished and thus protect the lamp.

The burner is interchangeable with the regular types of acetylene burners used in lamps, and consists of a hexagon block into which is secured a tube bent as shown by the illustration. Gas is admitted to this tube through a nozzle from four to six thousandths of an inch in diameter, and mixes with atmospheric air, which is drawn into the burner through four holes about one-sixteenth inch in diameter, located close to the nozzle. The button consists of a thin brass tube thirteen-sixteenth inch in diameter and one-quarter inch long, having an annular groove in the centre for holding the light giving material with which it is filled. This material resembles a combination of pulverized marble and asbestos, which has been compressed. The button is secured to the burner by means of a wire clip encircling it. The ends of the clip fit into a tube secured to the top of the burner by a stud and nut. This serves to hold the button in the focus of the mirror of the lamp, and the flame being directed against the side of the button nearest the mirror, that is, toward the front of the lamp, the likelihood of cracking the mirror by the flame is therefore entirely eliminated. In addition to the automobile type burner

WUNDER BUTTON HEADLIGHT.

described, the company will shortly begin the manufacture of apparatus suitable for interior and exterior garage illumination.

# The Rohrbacher Auto Power Tire Pump.

The Rohrbacher Automatic Air Pump Company, Ltd., corner G and Third streets. Blaine, Wash., are marketing a power air pump which, with slight changes in the supporting brackets, can be fitted to almost any existing car. The pump is driven by means of a paper friction pulley from the engine flywheel, being put into engage-

ment by means of a lever. The pulley shaft lies in the centre line of the pump cylinder, and extends into the crank casing, where its rotary motion is changed into a reciprocating motion. The pump is of the single cylinder type, the cylinder being provided with circumferential cooling flanges at its outer end, and inlet openings at the inner end of the stroke. The outlet is located in the head of the cylinder

ROHRBACHER TIRE PUMP.

and contains the usual check valve. The evlinder has a bore of 11/2 inch and a stroke of 2 inches, and the pump is claimed to inflate a 31/2 inch tire to 70 pounds pressure in less than two minutes. By means of gearing inside the crank case the speed of the driving pulley is reduced in the ratio of 4 to 1, cast steel and bronze gears being used. The pump is claimed to deliver any pressure up to 200 pounds, and a gauge is furnished to register the pressure.

The Demotcar.
The Demotcar Company, of Detroit, has just been incorporated under the laws of Michigan. The company is planning to manufacture a small runabout in large numbers to sell at a moderate price. The name is a contraction of the words Detroit Motor Car Company. Detailed information regarding the company and its product will be given in an early issue.

# The Marmon Touring Body.

In the body of the 1910 Marmon car no wood is used except for the mahogany dash, the floor, and a thin strip between the frame and the body. All the rest of the body is of metal, the lower section being of cast aluminum and the complete doors of the same metal. This construction does away entirely with the possibility of shrinking and warping, and consequent misfits of doors, seats, etc. At the same time it gives considerably greater strength to the body construction.

## New Franklin Features.

The H. H. Franklin Manufacturing Company, Syracuse, N. Y., have just issued a bulletin to dealers containing their 1910 announcement, from which we take the following:

A new air cooling system will be used on all 1910 motors. Each cylinder will be provided with vertical cooling flanges, and surrounded with a sheet metal casing open at the top and bottom, and a diaphragm will connect the casings and form an air-tight compartment with the engine boot. At the rear of this compartment is located a flywheel fan which draws air through the casings surrounding the cylinders, whereby the engine is claimed to be perfectly cooled. No front fan is used,

Extra large tires will be used on all 1910 models, viz., 37x5 inch and 36x41/2 inch on the Model H, 36x41/2 inch and 36x4 inch on the Model D, and 32x4 inch and 32x31/2 inch on the Model G. The company state that it will not be necessary to carry extra tires on any of their 1910 models. No spark lever will be fitted to any of these models, the spark point being fixed on all, the same as it was in the 1909 Model G. Quite a variety of bodies will be furnished with the different models, as follows: The six cylinder, 42 horse power chassis will be equipped with seven passenger touring, close coupled, double rumble seat runabout, and limousine bodies; the four cylinder, 28 horse power chassis will be equipped with five passenger touring, close coupled, double rumble seat runabout, landaulet and limousine bodies; the four cylinder, 18 horse power chassis will be equipped with four passenger touring, six passenger town car, runabout (with hamper), single rumble seat runabout and double rumble seat runabout bodies.

# Two Imperial Companies.

The Imperial Motor Car Company has been organized at Hamilton, Ohio, with \$500,000 capital, and the following officers: G. A. Rentschler, Geo. H. Helvey, C. U. Carpenter, Geo. Stanley Helvey and Fred D. Rentschler. Mr. Carpenter is president of the Herring-Hall-Marvin Safe Company and George Helvey was formerly general superintendent of the Hooven, Owens & Rentschler Company, while Stanley Helvey was formerly connected with the Allis-Chalmers Company, of Milwaukee. The new company has purchased the old Snider paper mill property near the fair grounds.

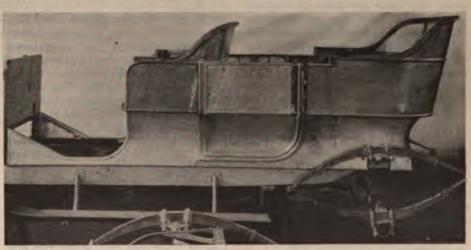

The Imperial Automobile Company has been organized at Jackson, Mich., to succeed the Jackson Carriage Company. The following officers were elected at a recent meeting at the office of the company on Washington street: B. M. Delamater, president; H. S. Reynolds, vice president; Franklin Tiffany, treasurer, and T. A. Campbell, secretary. These officers were also in control of the Jackson Carriage Company during the two years of its existence. The new company will continue the manufacture of the line of carriages turned out by its predecessor, and will in addition produce two models of automobiles, a 30 horse power car to sell at \$1,500 and a 40 horse power car at \$1,800.

# Rambler New York Agency Taken Over by the Manufacturer.

Thomas B. Jeffery & Co., who last year established a New York branch to control the sale of Rambler cars in New York and contiguous territory, have taken over the retail business of the Rambler formerly handled by the Homan & Schulz Company, New York city, and moved it to 38-40 West Sixty-second street, where the wholesale depot has been located for the past ten months. The Rambler now has branches located in Boston, New York, Cleveland, Chicago, Milwaukee and San Francisco. At each point a complete line of current models is exhibited, together with a full line of

# To Market Kenerson Dynamometer.

The transmission dynamometer invented and patented by Prof. W. H. Kenerson, of Providence, R. I., is now being built and marketed by the Builders' Iron Foundry of that city. The dynamometer was illustrated and described in a paper read by Professor Kenerson at the meeting of the American Society of Mechanical Engineers at Washington in May last, which paper was reprinted in THE Horseless Age of May 19.

MARMON 1910 MODEL TOURING BODY.

## Helical Timing Gears.

Editor Horseless Age:

It is a fact, becoming better known each succeeding year, that correctly cut helical gearing (commonly, though erroneously, called spiral gearing) will run with far less noise than equally well cut spur gearing. That this knowledge is not wider spread, or in fact universal at present, is due naturally to the fact that the high development of hobbing machinery and the hobbing process is comparatively recent; as it is only by this process that perfect helical teeth can be machined.

The reason that the helical tooth is quieter in action than that of the spur gear exists in the fact that the angle at which this tooth is cut permits only of its gradual engagement, and as this angle is usually great enough to permit the following tooth to enter contact before the first has quite passed out of mesh, we derive what may be characterized practically a continuous contact.

Regarding the specific points to be taken care of in adopting helical gears for motor timing, the Grant-Lees Machine Company, of Cleveland, suggest as an ideal outfit the following:

Cam shaft gear, of 20 point carbon steel with no recessing.

Magneto gear, carbon steel, with no hubs. Idler gear, of cast iron, with no hubs.

It is suggested that no recessing be done in the steel gears, because, while lightening the motor is of undoubted importance, the amount of lightening possible here is really negligible, but the increase in cost for such recessing is not. Hubs should be avoided where possible, for the same reason of cost, as they prevent ganging the gears for cutting.

An important point, then, that should be held in mind by the engineer when designing helical gears is to produce blanks which can either be made automatically from the bar or, in case the blanks are of cast iron, a simplicity in construction should be carried out so as to allow ganging of gears and the smallest number of settings of the machine for hobbing and facing them.

Cast iron is recommended in place of the once customary bronze, as it is cheaper than bronze, and for this service in no way inferior. In fact, it has this one advantage, which is of higher value than at first might appear: If a bronze gear is dropped or struck accidentally, it is liable to be harmed to an extent not noticeable on inspection, but will show up later in action. If a cast iron gear is not broken by a similar accident, it will be found as good as before.

most any angle of the teeth from 12 to

20 degrees will give satisfaction, as the end thrust resulting from an angle within these limits will for this service (timing gears) be slight enough to be negligible. A pitch from 9 to 12 is usually employed, and approximately a one inch face on the gear.

That the engineers of the automobile world are coming to regard highly the advantages of helical timing gearing is well instanced by the fact that the Grant-Lees Machine Company will in 1909-10 cut timing gears of this type for something over 20 per cent. of the American automobile manfacturers (this percentage practically covering the field), which, as their use was almost unknown four years ago, certainly shows a steady and substantial growth in popularity and appreciation.

ERNEST L. SMITH.

# Horseless Age Vehicle Speed Chart. Editor Horseless Age:

Referring to our former correspondence with you in regard to "vehicle speed chart,"

quires to be perseveringly dinned into the ears of the automobile investor. It is his only insurance for his money.

No business man will embark in trade without ensuring that he can buy his merchandise, yet the too prevalent trust in the ability of the automobile engineer to produce a marketable finished article at the first shot is just as foolish. The trial shot must be had—it pays everyone. No good automobile engineer will allow himself to exhibit such overweening self confidence. The rest are the kind who encourage the investor to waste a large part of his capital, thus begetting a feeling of insecurity throughout the trade and a want of support, induced by Investor A hearing how much Investor B lost in "automobiles,"

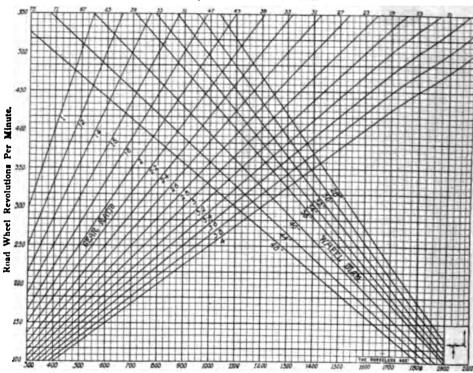

HUGO C. GIBSON.

# Incarcerated for Loss of Number Tag.

Editor Horseless Age:

Last Saturday afternoon I was, with my wife, driving my automobile along River-

Vehicle Speed in Miles Per Hour.

Engine Revolutions Per Minute.

which was published in THE HORSELESS AGE in the year 1907, we would ask whether, as stated in your letter, you have ever enlarged this chart for greater ranges of engine revolutions and of vehicle speeds. If such is the case, we would be pleased to have a copy of this chart sent us.

E. DE N. SANDS. extended, is printed

[The chart, suitably extended, is printed herewith.—Ed.]

# Haste in Marketing New Models. Editor Horseless Age:

I noted your editorial on "Injudicious Haste in Marketing New Models" in your issue of July 7 with much satisfaction, inasmuch as it is my belief that that note re-

side drive when I was halted by a bicycle policeman, who informed me that I had no license number displayed. This was the first knowledge I had of the fact, as the number was on the machine when I started from the Cimiotti Garage. However, evidently the wire had broken and it had dropped off. I was placed under arrest and taken to the police station on rooth street near Amsterdam avenue and locked up in a cell for nearly an hour until my wife returned with a bondsman for \$500.

It seems to me the law should be modified to the extent of allowing the lieutenant at the station house some discretion as to the incarceration of a prisoner pending arrival of bail. I understand he has none.

It seems absurd to sequester a man in a cell under such circumstances. The truth of my story could have been easily substantiated by the least investigation, inasmuch as my garage and my residence were within a few blocks of the station house, and both had telephones. I myself am well known. I am in business in this city and president of several large corporations, and until recently was president of one of our national banks. My automobile was in custody of the police during the episode, and was of itself a sufficient guarantee that \$500 bail would be furnished. I was not allowed to telephone from the station house nor permitted to go outside in the custody of an officer to do so. It is not within the discretion of the lieutenant to allow a prisoner to telephone, I was told.

The next morning Judge Barlow, of the Fifty-fourth Street Court, gave me an immediate discharge on hearing the testimony.

It is such cases as these that destroy in every class of society all reverence for the law in America and go to explain why automobilists in particular make such strenuous efforts to escape arrest.

"ZANZIBAR."

# Compression in Two Cycle Motors. Editor Horseless Age:

Being a reader of your paper I want to ask the following question: How many pounds compression are necessary for a 4x4½ inch two cycle motor? H. A. B.

[The most practical compression pressures are about 8 pounds per square inch in the crank chamber and from 70 to 75 pounds per square inch in the cylinder.—Ep.]

# Offsetting Cylinders.

Editor Horseless Age:

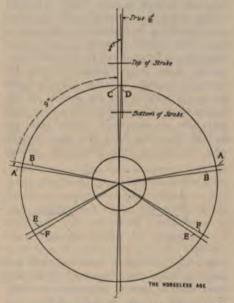

Nothing could be more interesting than the discussion of such a subject. It is important, because nothing has been clearly proven so far, inasmuch as such tests as have been made have usually been subject to the objections that the elements of accuracy have not been present. This does not say that they are all inaccurate, but that they may be, and, therefore, should be taken cum grano salis.

The article by Mr. McIntosh in your issue of July 21 is valuable as far as it goes, as showing that there may be something in offsetting for low speed engines, and I firmly believe there is, but such tests as are reported therein are at least liable to be misleading for the following reasons:

An engine which will show an increase of horse power by advancing the spark to 80° early must be using a very polluted mixture, and consequently be unsuitable. But, on the other hand, this figure was probably merely a mechanical measurement of the assumed time of ignition. Hence the question arises, Where did the spark occur, and if it occurred at a certain place during the forward operation of the engine, did it also occur at a similar angularity dur-

ing the reverse operation? Obviously it did not. The accompanying sketch shows clearly why not, when taken in conjunction with the fact that your contributor arranged for the spark to occur at certain fixed points irrespective of the direction of rotation of the engine, no allowance being made for the effect of the offset on the spark time. In my sketch the lines A, A' represent the time of ignition as used by your contributor, and which would be correct for a straight engine, while B, B' show the correct time that should have been employed. The result of this is that when the engine was running astern the spark was retarded over 7-16 inch (measured on the 13 inch circle) as compared with its position when going ahead. This would account for considerable lost horse power.

Again, the offset produces similar results as to the time of opening and closing the ports; for instance, the ports show a dif-

ference of ¾ inch (measured on a 13 inch circle) in the position they open and close as compared with a straight engine, and no one knows what effect that would have except that all ports open earlier on the downward stroke and close earlier on the upward stroke when going astern as compared with going ahead. F, F' show the timing on a straight engine, and E, E' with ¼ inch offset. It is fair to assume that one of these timings, either E or E', is correct, and that the correct one is designed for going ahead; therefore poorer results are obtained when going astern.

Now, these variables render all results useless, and your contributor recognizes this when he says, near the end of the article, that "the engine is harder to control when changing from reverse to forward operation," etc., thus showing that the conditions are not the same.

Finally, no tests on this subject are of value unless the engine may be worked at high speed, say 1,500 r. p. m., for automobile engines are essentially high speed engines, and all investigators agree that offsetting decreases in value as a friction re-

mover as speed increases; and, further, it introduces a decided want of balance, a most undesirable result.

I heartily indorse any attempts to settle a vexed question, but it seems a pity to attempt a solution by inaccurate and misleading methods. Hugo C. Gibson.

# A Few Thoughts on Driving.

Editor Horseless Age:

Almost anyone thinks he can drive a horse. Yet how few really good drivers do we see on the road! The matter seems simple enough. Just hold the lines, and when you wish to turn to the right pull on the right line, and if to the left on the other; how simple it all is. But, alas! that is not all of it. Should the horse refuse to go, of course there is the whip. Should he back, again the whip. It really is absurd to say that everyone is not a born driver, And yet why is it that we see men and women driving horses who we know cannot drive correctly? Instead of keeping the lines taut, how often do we see them hanging down over the dash, and the horse doing the driving himself? How frequently do we see women, and even men, who are supposed to know better, holding the hands far apart and extending them to the right or left when they wish to turn, or even raising them above the head when they wish to stop?

It is a beautiful sight to see a good driver handle a fractious team in a bad place, always keeping them under perfect control with apparent ease. But let any auto driver give his experience in meeting and passing teams, and we will discover how few really good drivers there are on the roads. I recently had a little experience with one of the exceptions.

I met a young man and lady in a buggy in a narrow place on a grade with a ditch on either side, and the team was young and fractious. I stopped my car and engine as far to one side as I could, and sprang out to assist him by, but the team sprang to the right with their fore feet down in the ditch, where he held them steady enough for me to assist the lady to the ground. Then he swung the team around as it were by mere force of the lines, lifting them out of the ditch, and coming up facing me once more when I led them dancing by the machine to receive his thanks for my courtesy. But the thing which struck me most forcibly was his masterful management of his horses. He did not touch the whip, but instead talked all the time to the team.

It is not often we meet such drivers, and when we do meet them, if we give them a chance, such as we would like ourselves under similar circumstances, they always appreciate it, and feel kindly toward us for the thoughtfulness. It is not courtesy thrown away to do all that we can to assist horse drivers when we meet them, and a little care shown at such times will do far more to settle prejudice among horse-

men than all the talking we might do from now till doomsday.

But I did not set out to tell about the correct way to drive horses, as that is something which can only be learned by long practice, and all the lecturing in the world will not make good drivers of some men. I wish to mention a few things which ought to be known and practiced by every driver of an automobile.

In the first place, we all know that the horse is a dangerous animal when once frightened, and no man can tell just when he is going to scare. If we who drive autos would only give the horse driver the best of every meeting, we would do more to disarm the autophobe than we could in any other way. It is a duty we owe to the community to help the other fellow in every way possible, when we see that his team is frightened. In fact, it is much better to do more than is required of us by law than to be bumptious and claim every right we can, for the simple reason that our horses will not scare, and the other fellow's will. If we rush recklessly by, apparently not caring what occurs to the other man, we are guilty of gross negligence and a lack of courtesy which ought to drive us from the highways. The burden of responsibility rests with the driver of the automobile, for he can never tell just what the team or its driver will do. It is unwise to expect anything of him, for you do not know anything about his skill or courage, and a little inconvenience for you may save a bad accident which endangers life or limb. The fact that it is the other fellow's life that is endangered makes no difference, so far as responsibility is concerned. It is far better to take even unnecessary precaution than to have to regret all one's life that it was not done.

We read a great deal about automobile accidents in our papers, and think nothing of them, but nine times out of ten they arise from too little caution on the part of the automobile driver. Too much speed at the wrong time, taking turns carelessly with no regard to conditions, taking chances merely for the fun of it, or neglecting to look after the condition of brakes and other parts of the mechanism, are the greatest causes of accidents to be met with. And vet young men who have not learned the need for caution, or the common courtesies of the road, are constantly doing things which would make an old driver shudder. It is criminal to allow such men on the road. It not only endangers the lives of those who ride with them, but, what is worse, it puts the lives of other road users in jeopardy unnecessarily.

I do not wonder that there is a certain class of road users who are constitutionally against the use of the automobile. The fault does not lie so much in the fact that horses will scare as in the careless and unwarranted use of the auto. Let us not be deluded by the cry of the thoughtless that we have as much right to the road as has orseman, but remember that all users

of the public highway are morally in duty bound to protect the rights of others as well as to maintain their own. If the rights of anyone are to be interfered with let it be those which we claim, rather than to impose upon the other fellow. I do not mean to preach, but to ask for simple justice, and that moral courage which would rather suffer an injustice than to impose it upon another. Do right, be courteous, kind and considerate, and the roads will be safer, and prejudice will die a natural death.

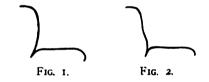

E. H. VAN PATTEN.

[It should be pointed out that our correspondent writes from the State of Washington, where horses in general are not "automobile broken" to the same extent as in the East.—ED.]

#### Comfortable Seats.

Editor Horseless Age:

I have noticed a considerable difference in the shape and dimensions of the seats of automobiles, irrespective of the cost of their construction. I refer to the outline which would be produced by a vertical foreand-aft plane section passed through the centre of the seat. In some cases the backs are nearly vertical, like the pews in an old-fashioned church; in others they slope back more like an easy chair. Some seats are so high above the floor that many persons who are only a little below the average

height when sitting in them find their feet dangling in the air. The depth of the seat from front to back is frequently too small. Such seats are not restful, unless to unusually short persons.

An important feature in which carriages and railroad cars, as well as automobiles. differ much is in the shape of the back. In many cars, perhaps the majority, the back is shaped like Fig. 1. I believe, however, that a shape similar to that shown in Fig. 2 will be found more comfortable by the average person. It produces the effect sometimes sought with a chair by placing a pillow behind the lower part of the back. I first noticed the comfort of this shaped back in a Locomobile of 1906, and afterward in some railroad cars and carriages, but I have not had any opportunity of observing to what extent this shape is used in well known cars of the present time. Are there not some shapes and dimensions which are "standard," and which give the most comfort to the average person? On a long journey defects in the shape of the seats produce as much or more fatigue as improper springs. Can you give me any information on this subject?

W. S. DAY.

[We doubt whether there is anything "standard" in automobile body designs. Per-

haps some of our readers experienced in this line of work can throw light upon the subject.—Ep.]

Does Retreading Pay?

The Fisk Rubber Company make the assertion that 90 per cent. of the old tires which are retreaded ought not to be, as far as an owner's interests are concerned. The manufacture of rubber and the repairing of tires is a science that takes years to master, yet apprentices will work a few weeks in a garage or tire repair shop, and, thinking they know it all, branch out in business for themselves. Some of them will undertake to retread any old worn-out shoe that is brought to them, for if they were conscientious and advised a customer that the repair would not be worth while they would starve.

An owner may have a casing that has given him a few thousand miles of good service, and is still apparently in good condition. He consults the manufacturers of that tire in regard to having it retreaded, and they advise against it on the ground that the inner fabric is too much worn, and affirm that a new tire would be more economical for him. The motorist then goes to the nearest "tire repair expert." The latter informs the visitor that the tire company is all wrong. The Fisk Company state that repairers, as a rule, use only the poorest, cheapest quality of scrap rubber and the crudest methods. Should the old, played out, retreaded tire last only a week or so. due to improper vulcanization and curing, the motorist has no redress from the repair man, who does not guarantee his work, and coolly tells the owner his tire "was no good in the first place." The unscrupulous repair man has no reputation to lose, and is not greatly worried.

If a tire has not been driven at the proper degree of inflation it is almost certain that the fabric has been strained so that recovering is useless. In view of the fact that to vulcanize and cure a tire requires fifty-five minutes of heating at a temperature of 55° centigrade, it is easy to understand that this process is going to weaken fabric that has already been strained.

Tire manufacturers, as a class, are honest with their customers. If a tire can be retreaded and give hundreds of miles additional riding, it speaks well for the manufacturer's product, and he is glad to be able to do it. When a manufacturer advises against it, however, it is the best plan to take his word and buy a new shoe. We are informed that during the past two years a motorist of Orange, N. J., has had two Fisk rear casings recovered three times, and has gotten more than 13,000 miles out of each of them. He is one of those who know how to keep their tires inflated properly.

The Royal Automobile Club of Great Britain and Ireland now has a membership of 16,307, an increase of 2,302 during the past half year. The club has 96 clubs associated with it.

## Commercial Applications.

#### Electric Trucking at a Big Textile Works.

BY ALBERT L. CLOUGH.

The Amoskeag Manufacturing Company, Manchester, N. H., who are one of the largest producers of cotton and worsted textiles in the country, introduced electric haulage into their plant about two years ago. A 3 ton Columbia truck constituted the original installation, which has grown so that it now includes four trucks of capacities ranging from 1½ to 5 tons, three of these being Columbias, and one—the latest accession—a product of the General Vehicle Company.

Specifications are now in preparation for another vehicle, and two or three more will, it is understood, be purchased in the near future. It evidently is the intention of the management ultimately to entirely supersede horse haulage within the plant, which covers about 150 acres, and includes about 15 miles of concrete and block paved

Those in charge freely admit that there is a substantial saving effected by the use of electric vehicles, as compared with horse drawn drays, and the rapid extension of the service would indicate that this economic advantage is being embraced.

#### GARAGING AND MAINTENANCE.

The garaging and maintenance of this fleet of cars evidence advanced practice, and a few details may be of interest.

The garage affords a floor space 70x90 feet in extent in a brick and steel building, with tar concrete approaches. The floor is of cement concrete, drained to a cesspool with sewer connection. The fin-

ish of the interior is white, except that a dark green is used on walls and posts to a height of 4 feet. General illumination is afforded by enclosed arcs, and each post carries a receptacle from which flexible cords reach every portion of the building. All wiring is in underground conduit or in molding. Automatic sprinklers are installed, as well as a standpipe, with hose sufficient to reach to any part of the floor.

Heating is by overhead radiation from the company's steam plant, and there is a hot water supply to the employees' toilet room and to the washers' sink.

A compressed air supply is derived from the company's air pressure mains for cleaning and for tire inflation.

#### EQUIPMENT. "

Around the sides of the room are arranged the following: An oil cabinet containing three 60 gallon pump tanks, for kerosene, cylinder and lubricating oils, and a grease supply; private lockers for each chauffeur; drawers for general supplies; individual lockers for the spare parts of each car; spare solid tires for each car, accessibly fastened to the wall; compartments for waste; shelves for spare cells; racks for metal stock to be used for side wires for the tires; a stock of side wires brazed up for use, as well as a compartment to contain the carboys of electrolyte; a long bench supplied with vises and a full kit of machinist's and electrician's tools. Around the ceiling runs a special pipe carrying distilled water, which leads from the distilling apparatus to four carboys located upon shelves carried by the posts of the building. Any particular carboy can be filled from the distiller by opening a valve in its branch to the main pipe, and each carboy is fitted with a rubber draft tube, with pinch cock, through which distilled water can be obtained by gravity. These tubes reach all parts of the floor. The still itself consists of a water jacketed worm fed with clean steam from the main steam supply. \*

Toward the back of the floor is located the drained concrete washstand, and under each car is a drip pan made of galvanized iron, coated with asphaltum, to resist the action of spilled electrolyte.

#### CHARGING.

To one side of the main runway is located a track upon which, a car may be run. Between the guide rails of this track is the platform of a direct acting hydraulic elevator used in changing batteries. A car is run over the elevator, the battery lifted by the elevator and unhooked, and the elevator lowered, when the car may be run out of the way by hand. A chain falls on an overhead track is used to lift and convey the batteries to wheeled trucks.

The inspection pit is conveniently located close to the elevator, so that an inspection may be made without moving the car materially.

A tire setting machine is installed, capable of handling the largest wheels and tires, and a chain falls is provided above it to lift the wheels into place.

Portable tanks for oxygen and hydrogen, together with the necessary tubing and blowpipes for lead burning are also at hand.

The charging facilities are as follows: Direct current at 125 volts is obtained from a 50 horse power motor generator set, consisting of a 550 volt, sixty cycle, three phase General Electric motor, direct connected to the direct current generator. This set can be operated either by current from the company's 10,000 kilowatt private plant or from the lines of the local lighting company. The switchboard consists of the feeder panel and ten charging panels. The former carries a total alternating circuit and a total direct current ammeter and circuit breaker for the direct current side, together with a ten point back connected

ELECTRIC TRUCKS USED BY AMOSKEAG MANUFACTURING COMPANY.

rotary voltmeter switch and voltmeter for indicating the voltage of the charging circuit. There is also a Bristol recording ammeter, the cover of which is locked, and its record acts as a check upon the employees as to the times of starting and stopping the charging and the number of cars on charge.

Each charging panel carries its individual circuit breaker and ammeter and double pole, double throw switch. One position of this switch connects to the charging bus and the other to the discharging bus. In the latter is an adjustable water rheostat, consisting of a wooden tank carrying two movable copper plates in dilute sulphuric acid. This tank is fitted with water supply and a sewer connection. A total ammeter is cut into the discharging circuit. Back of each charging panel is a Cutter-Hammer rheostat of sufficiently wide range as to vary the current from 60 down to 5 amperes. This admits of the charging of ignition batteries as well as the vehicle batteries.

Charging plugs are located upon each post in the garage, a special very heavy cable being employed. Special holders are provided for these plugs, when not in use, so that they may not be defaced by rough usage.

Sand boxes are provided upon these cars and a large sand supply is carried within the garage. The sand to be used is passed through a compartment in which is a steam coil, so that it is thoroughly dry before being used and its free feeding is assured.

#### SPARE EQUIPMENT.

The spare equipment consists of three complete batteries on trucks, ready for instant use, a full line of spare tires, spare chains and gears, controller fingers, brush rigging and other small parts, spare cells and elements and the like. The policy is followed of standardizing the equipment, as far as possible, in order to minimize the necessary stock of spares.

When a battery is put upon the spare list it is always charged at a very low rate, not exceeding 10 amperes, as time is no object and beneficial results are thus obtained.

The nightly service charges of the batteries are of twelve hours' duration and at a considerably lower rate than that specified by the battery manufacturers. Hourly readings of voltage, amperage and temperature for each battery are taken and the reports turned into the office,

#### INSPECTIONS.

Every night, after 6 o'clock, the attendants make an inspection of each car. This includes the examination of commutators and controllers for burning and the filling of such cells as need it with distilled water. A certain cell is selected from each battery and known as thes pilot cell. During charge, at stated intervals, the gravity of this cell is noted and is turned in on the report. Any chauffeur noting any defect in his car describes it upon a special trouble card, which is turned into the office at the end of the day's work. This card, when

GARAGE OF AMOSKEAG MANUFACTURING COMPANY, MANCHESTER, N. H.

approved, is given to an attendant with instructions to rectify the defect. Chauffeurs report for duty in the morning in time to do the daily oiling and a general inspection. From Saturday night until Monday morning each car is given a thorough mechanical inspection, which includes gears, chains, brakes, bearings and all other parts. During the charge, which takes place within this period, the gravity of each cell of each battery is taken and reported. This locates at once any "sick" cells, and if such are found the battery is removed, a spare one substituted and the defective cell cut out at leisure. The voltage of each individual cell is taken at the same time with the gravity, and is important in locating trouble. On these weekly inspections it is frequently found necessary to strengthen the electrolyte, as pure water only is added during the week, and spraying and the rapid evaporation resulting from heavy work in very warm weather call for a considerable amount of replenishment of liquid during the week. On the weekly report sheet each cell has a number. A blue print of each battery is posted in the garage, with each cell of each battery shown numbered. This makes identification easy and certain, and if a cell of a certain number is ordered cut out it can readily be done without chance of mistake.

#### WASHING OF BATTERIES.

It is the practice in this installation to wash each battery three times during its life, replacing all wood separators and performing the washing of the plates with a fine spray of water, under light pressure. The time for a washing is indicated by the rise of the deposit in the bottom of a certain cell in each battery that is subjected to the maximum heat conditions. This cell is kept under observation, and when its deposit rises to within one-quarter

inch of the bridges the battery is put out of service for washing.

Rubber gloves, high rubber boots and rubber aprons are furnished the men who do this work. After the battery is washed and assembled it is given a slow charge, to its full capacity, but it is not at once sent out on a car. It is first discharged and the discharge capacity must be up to the standard or it will be reserved for further "bringing up."

It is the experience of F. A. Clark, the engineer in charge of this service, that it is advisable to entirely renew a battery—negatives, positives and separators—at the end of one year, under the conditions here met with. Each car is run from 20 to 25 miles per day for 300 days per year, and thus each battery gives a mileage of from 6,000 to 7,500. In this installation it has been found inadvisable to renew the positives only and to use the negatives with another set of positives.

On the average, one set of solid tires, of the particular make used, lasts for 5,000 miles.

All cars are washed each Sunday, no more frequent washing being required, as nothing but pavement is traversed. Tops are carried only in rainy or very hot weather, and are kept slung to the ceiling, on falls, at other times.

All loading platforms correspond in height to that of the cars. The operators are mostly former horse dray drivers who have been in the company's employ for a considerable time.

#### ROUTES.

Each car, with one exception, has a regular route, which is followed day after day, until orders are changed. That the rather unusual precautions taken in the operation and maintenance of these trucks secure excellent reliability in service—a qualification which is of exceptional importance here-is shown by the following figures: One truck was out of service 44 hours out of 4,500, and two others 65 hours and 18 hours, respectively. In other words, they were out of commission about I per cent., 1.4 per cent, and 0.4 per cent, of the time they were in service. The equipment of horses for a truck has been found to be out of service, for the purpose of shoeing alone, a greater proportion of the time than this.

The new trucks, with single motor equipment, commutated field control, silent chain transmissions and anti-friction countershafts and wheels, are found, in this service, to do the same work with a 30 per cent, less expenditure of energy than the older trucks with double motor equipments, series parallel battery control, spur gear reduction and plain bearings.

One other business vehicle in the service of this company is a 18-22 horse power A. L. Co. gasoline taxicab, which is kept busy in taking the officials on business trips and conveying visitors to and from the railway station.

#### Milwaukee's Municipal Cars.

The Milwaukee (Wis.) Common Council has voted to purchase a runabout at \$1,000 for the health department. Commissioner Bading believes his force of inspectors will save 50 per cent. all around. The council has also authorized the purchase of a Pierce-Arrow touring car for the Milwaukee police department, bureau of detectives. The department has in use a motor patrol wagon. The purchase of a Peerless touring car for the joint use of council committees and the Board of Public Works, delayed several months by injunctions, finally has been authorized, and the car has been paid for.

With more than fifteen municipal cars in Milwaukee, and the growing possibilities of city officials in the direction of using the cars not always on strictly official business, an ordinance has been introduced providing that all cars shall be labeled in large letters with the name of the city and the department using the car. This would effectually stop the use of the machines for social occasions.

#### Minneapolis Now Has a Motor Patrol Wagon.

The city of Minneapolis has been using a Rambler Model Forty-five car, equipped with a special body, in the patrol service for the past two months. We are informed that the car has been in active service every day, and on one occasion eighteen people, including four officers and fourteen prisoners, were carried after a raid on a gambling outfit 3 miles outside of the city. The car was built to carry but ten passengers. The vehicle is electrically lighted, and is equipped with the Rambler spare wheel. A duplicate of this car will be purchased by the city of Minneapolis for use as an ambulance.

Progressive Cemetery Company.

The Forest Home Cemetery Association, of Milwaukee, Wis., owning the largest cemetery in the Northwest, has decided to purchase a motor bus for the convenience of the thousands of daily visitors.

#### Commercial Notes.

The Frank Bird Transfer Company, Chicago, Ill., have placed an order for three 24 horse power taxicabs with the Coppock Motor Car Company, of Chicago. The first of these cars have been delivered.

H. W. Horton and T. S. Hubbard, of North Wilkesboro, N. C., will shortly open an automobile service between North Wilkesboro and Taylorsville, a distance of 20 miles, part of the road leading over a

The post office of Fall River, Mass., will shortly put three Maxwell cars in service for the collection of mails. A request for the authorization to use automobiles for the work was made to the Post Office Department at Washington some time ago.

Harry E. Pence will start a taxicab service with twenty-five Buick cabs of 40 horse power in Minneapolis, Minn., on August 1. The cabs were to have been delivered on June 15. The rates charged will be the same as those now charged in New York, viz., 30 cents for the first half mile and 10 cents for every quarter mile thereafter.

Howard V. Wilcox, of Atlanta, Ga., plans to inaugurate a motor bus service in Ansley Park, a suburb of that city. Mr. Wilcox plans to secure a sixteen-eighteen passenger bus, and to run it on a fifteen minutes' schedule. A reserve car will be kept in the garage for special service, while the regular car will stop at any residence to which it

The Berks Auto Traffic Company has started an automobile service between Reading and Bernville, Pa. A 60 horse power sixteen passenger Manhattan bus is used, and starts from the Farmer's Hotel, Fifth and Washington streets, Reading. Three round trips will be made per day. The distance is 14 miles, and is covered in less than an hour and a half. The single fare is 60

Wm. Bomsack, a rural mail carrier de-\* livering mail from Grand Rapids, Mich., who recently purchased a runabout with a special interchangeable body, now covers his route so quickly that he is able to conduct an auto livery business in his spare hours. He usually leaves the post office at 8 o'clock a. m., and returns at 10:30 a. m., where formerly, with a horse and buggy, it took him from 8 a. m. to 3 p. m. to cover

#### Rapid Company Increases Capital.

The Rapid Motor Vehicle Company, Pontiac, Mich., at a stockholders' meeting held on July 20 decided to increase its capital stock from \$250,000 to \$500,000. The new capital will be invested in additional buildings and machinery, according to plans

published in our last issue. It is reported that \$200,000 of the new stock was taken by W. C. Durant, of the General Motors Company. This will leave the control of the Rapid Company, for the present at least, in the hands of the Pontiac interests.

#### Deficit of the Crown Point-Lowell Races.

It now appears that the recent Crown Point, Ind., races will not pass into history without a sequel in the form of a lawsuit. F. J. Lewis, of the Lewis Manufacturing Company, which put the Crown Point-Lowell course into shape for the races, has announced that he is preparing to sue Ira M. Cobe, president of the Chicago A. C., for a sum of approximately \$8,000, part of the money due for work on the course. The contract made between Mr. Cobe as president of the club and the Lewis Company was for \$21,600. The club paid approximately \$13,000 on the contract, and then ceased further payment, alleging that the Lewis Company failed to carry out its part of the contract and keep the course in good condition. The payment to the contracting firm was guaranteed by Mr. Cobe personally, and if suit is instituted it will be against him. The exact amount of the deficit caused by the races is not yet known. but it is thought to exceed \$30,000. It seems that some of the members of the Chicago Club thought that Mr. Cobe should bear the entire deficit, as he received practically all of the publicity resulting from the race. Mr. Cobe's friends assert, however, that he did not donate the cup for the sake of publicity. The Chicago Automobile Club's board of managers has unanimously voted that the club shall assume all the indebtedness resulting from the races, but that Mr. Cobe shall be permitted to aid in wiping out the deficit.

#### Consolidation Proposed.

It is reported that the Racine Manufacturing Company and the Piggins Brothers, of Racine, Wis., will be consolidated and engage in the manufacture of motor cars on an extensive scale. Piggins Brothers manufacture motors for the general trade, and have placed a number of cars of their own make on the market. The Racine Manufacturing Company has just arranged for the erection of a five story building. The new site adjoins the holdings of both companies,

#### New Motor Sleigh.

Otto J. Kirchen, of Hancock, Mich., has applied for a patent on a motor sleigh. The patent is expected to issue this month, and Mr, Kirchen will then endeavor to interest local capital in a \$25,000 company to place the invention on the market. The sleigh mechanism consists of two runners in front, to which may be attached the steering gear of any standard car. The rear of the sleigh is supported by two double runners, between which is placed a spiked chain wheel by means of which the sleigh is propelled.

## Motorist Gets Damages from Horse Driver.

One of the few cases on record in which a motorist received damages from a horse driver is reported from Crestline, Ohio.

J. M. Martin, of that town, accompanied by Mrs. Martin, was driving west on Bucyrus street in his automobile, when W. Kauffman, a farmhand, came along in a single buggy in the opposite direction. Mr. Martin kept to the right side of the road and yelled to Kauffman to stop or turn out, but the latter disregarded the warning, and the buggy and auto collided. The buggy was demolished and the auto injured. Martin entered suit against Kauffman for the damage to his auto, claiming Kauffman was at fault in not turning out. Kauffman engaged counsel to defend him, but when the latter learned the facts in the case he advised his client to settle, which he did.

#### Rulings on Ohio Law.

The Attorney General and the State Motor Vehicle Department of Ohio have recently made several important rulings regarding the application of the State motor vehicle law. The department has decided that when a member of a family owning a car drives the vehicle it is not necessary to take out a driver's license. Identification by tags is considered easy when the car is driven by the owner or a member of the family. The Attorney General, on the other hand, has decided that when a car is owned by a corporation and used by many of the officers and stockholders each one will have to provide himself with a driver's license as chauffeur, because the ownership of the machine by the corporation does not identify the officer and stockholder.

#### Anti-Taxicab Ordinance.

An ordinance has been introduced in the Milwaukee (Wis.) Common Council by Alderman Henry Smith, aged seventy-six years, prohibiting taxicabs or motor vehicles for hire from occupying any part of Grand avenue, and relegating them to the side streets. Mr. Smith says the streets are too valuable to be "obstructed" by these vehicles. The ordinance does not relate to hacks or cabs drawn by horses, and therefore it is unlikely that the council will discriminate by passing the measure.

## Want to Tax Autos as Personal Property.

At a recent meeting of the State Tax Commissioners and Supervisors at Riverhead, L. I., N. Y., it was suggested that all automobiles owned in, the county should laced upon the various town assessment rolls as personal property and taxed as such. If this was done it would certainly considerably increase the revenue of the county, but it is feared that motorists would attack the measure as discrimination, inasmuch as horses and carriages are rarely, if ever, taxed as personal property; and, besides, automobiles are already taxed in a way through the licensing law, and to exact a personal property tax would amount to double taxation.

## No Motor Vehicle Commissioner for Connecticut.

The Connecticut Senate has indefinitely postponed the bill creating the office of State Commissioner of Motor Vehicles. The original bill provided for a supervisor, who should be a deputy in the office of the Secretary of State. An amendment was offered which purposed to give the Governor the right of appointing a commissioner, who should have a deputy and an office staff. The amendment was defeated, and the entire matter indefinitely postponed. Automobile registrations will therefore continue to be looked after in Connecticut by Secretary of State M. H. Rogers.

#### Members of Owner's Family Need No Driver's License in New York.

Attorney General O'Malley, of New York State, has given an opinion of considerable interest to all motorists to Secretary of State Koenig, viz., that there is no provision of law requiring the owner of a motor car or any member of his family to obtain a chauffeur's license before operating his machine.

Legal Notes.

The police of the principal cities in Ohio wish to have the State automobile law amended so as to prohibit a motor vehicle from carrying more than one set of tags, because it is claimed that when a machine has more than one set it is confusing to the police and defeats the object of the tag provision.

It is reported that at the next meeting of the city council of Rochester, N. Y., an ordinance will be introduced regulating the fares which may be charged for taxicab hire, and providing for licenses for these vehicles. At present the city has no ordinance regulating the operation of these vehicles, and hack owners and others affected by them are complaining of unjust discrimination.

## American Congress of Road Builders.

A permanent national organization perpetuating the American Congress of Road Builders, with Samuel Hill, of Seattle, Wash., for president, was agreed upon just before the congress adjourned after its three days' session in the Good Roads Building at the Alaska-Yukon-Pacific Exhibition grounds. A committee of nine was ap-

pointed to make a report on plans for permanent organization and to name the time and place of the next meeting.

A motion that it be declared the sense and desire of the congress to make Mr. Hill president of the proposed permanent association immediately followed. Both motions were carried unanimously. The following resolution was passed and Mr. Hill was presented with a cane, the gift of the members in recognition of his tireless efforts in behalf of good roads:

"Resolved, by the first American Congress of Road Builders, that in Mr. Hill, president of the Washington State Good Roads Association, we recognize a leader whose wise, energetic and constant efforts in promoting the common welfare as affected by the improvement of highways command our highest admiration. Sparing neither time nor money, with voice or pen, Mr. Hill has given an impetus to a general movement for better roads in all of the States of the American Union and the provinces of Canada, which must inevitably produce lasting benefits.

"Resolved, that the thanks of the congress are due to him and are hereby expressed for the many courteous attentions which Mr. Hill has bestowed and which the members of this association will remember with keen appreciation."

#### New Timing Apparatus.

The Warner Instrument Company, of Beloit, Wis., is engaged in the construction of a new electrical timing apparatus especially for the Indianapolis Motor Speedway, and to be ready for the dedicatory events on August 19 to 21. The apparatus will cost \$2,000, but is to be a gift to the Speedway by the Warner brothers. It is the invention of Charles Warner, assisted by Walter Baker, of Cleveland, Ohio. It consists of chronometer, chronograph, a telephone system and several other devices used in speed recording, combined so that it will be possible to tell accurately at any time the speed and mileage of any car.

#### Seek to Hold Mason Company.

The Greater Des Moines Committee, of Des Moines. Ia., has made an offer to the Mason Motor Car Company of that city to dispose of \$100,000 preferred and \$50,000 common stock of the company within the next thirty days if the company will remain in Des Moines. The concern has been negotiating with a commercial organization of Waterloo, Ia., with respect to removing there, but it is now thought likely that it will stay in Des Moines.

The British Society of Motor Manufacturers and Traders has decided not to hold a commercial vehicle show in 1910. It also has decided to abandon the project of a collective exhibit of accessories at the Brussels World's Fair, owing to the little interest in the project shown by parts manufacturers.

## OUR FOREIGN EXCHANGES ➤

#### Magneto Derangements.

Magneto troubles may be divided into three classes, viz., those which stop the firing altogether in all the cylinders, those which set up misfiring in one or more cylinders, and those which lead to weak running and loss of power in all the cylinders.

#### I .- ENTIRE ABSENCE OF SPARK,

If the engine will not fire on the magneto when the switch is thrown across from the accumulators, or if no spark be visible at the plugs when the starting handle is briskly revolved, the trouble is of the first class. It is not safe to immediately infer the trouble is of this class if the engine refuse to start on the magneto, for it might be due to (a) gummy pistons, (b) dirty plugs, (c) any common valve or carburation defect, (d) a weak spark; and, therefore, the spark should be searched for at the plugs before proceeding to treatment. After proving beyond doubt that there is no spark at the plugs at all, we may take it for granted that the trouble lies in or behind the central revolving wiper of the distributor. (There is only one exception to this, and that an almost impossible occurrence, viz., a simultaneous derangement of all four plugs, or their wires, causing the current to travel via the safety gap on all four circuits, or to short circuit via the engine.)

We can easily discover if current reaches the distributor wiper by putting a finger on it, and revolving the starting handle. A smart but not really painful shock will be felt if the finger be laid on the tip of the metal shaft on which the insulated wiper is fixed. If this shock be present, and be smart—not a mere gentle tickling—the fault is found. It lies in the spring pehcil of the wiper, which is not making contact with the four segments it rubs against. The tip of the pencil should be freed from tough scale, and the spring behind it pulled out to give better pressure.

More probably, however, no current will be felt at the wiper. In this case, dismount the distributor and ascertain if strong current can be felt in the brush which transfers the current from the magneto to the wiper (revolving the starting handle gently, of course, during all tests for the presence of current). If current be present at this brush, but does not reach the wiper, there is a short circuit between tlese two parts. Such "short" will be discernible to the eye in every case after careful scrutiny, and will be due either to dirt, oil or water, or, alternatively, to a visible crack in the insulating material. A good cleaning or application of insulating tape will provide an easy remedy.

Next, supposing current does not reach this transfer brush. In 99 per cent. of such cases the fault will be found in the contact breaker, and will be visible to the eye. It may consist in (a) the platinum points not making or breaking contact, (b) no platinum on either of the screws, (c) a broken metal part, (d) a broken insulating washer, or (e) short circuits by water, oil or dirt.

The remedies for the last four derangements are obvious. For the first no universally applicable rule can be given, since there is a huge variety of contact breakers. Fibre enters into the composition of many, and fibre is obviously liable to wear. A replacement will set things right, if the maker's case of parts be on board the car. as it always should be. If not, a little ingenuity will generally suggest a "fake." Fibre is pliable, and often a liner of wood or tin can be pushed under a fibre cam to give it a more pronounced contour. In other cases, a strip of court plaster may be overlaid to raise the hump till a spare can be procured. The most difficult type to "fake" is that fitted with small fibre discs, in which case maker's correct spares are the only cure. In some cases mere adjustment of one of the two platinum headed screws will set the points making and breaking again. In others the same result can be achieved by sinking the fixed platinum point deeper in its bed, by filing down the bed, so that the diminished cam can still separate the points. The important point is to ascertain if the points actually break or not. When that is done observation can detect the reason of their not breaking, and ingenuity can generally atone for wear, and compel them to break once more.

Next, supposing there is no spark, even though the platinums are making and breaking contact correctly, and its parts. brushes, etc., are all clean and unbroken. In this event the derangement is very likely to be a job for the makers, and its discovery may even be a matter of difficulty to them. It should be understood that such a misfortune is indescribably rare. As a last resort the entire magneto should be carefully dismantled, according to the directions in the maker's booklet, which are usually very full. If the derangement lie in the interior of the condenser or the armature, it will be beyond an amateur's capacity to either trace or remedy it. But very possibly a loose connection, a cracked insulator, a damaged brush, or a film of oil, dirt or water will be discerned by the eye, in any of which cases the remedy is obvious. If an armature connection be visibly broken, as may be the case with either of two external connections on several makes, the greatest care will be needed in remaking the connection. If the broken tag of wire be pulled about further trouble will be set up, and, as a rule, a piece of wire, no longer than an inch, will have to be very gingerly spliced in and covered with several wrappings of insulated tape.

#### II.—SIMPLE MISFIRING.

When the trouble merely consists of misfiring in one or more cylinders, even a duffer may quickly find and apply a remedy. First, discover the errant cylinder or cylinders; short circuiting the plug terminal onto the cylinder head by laying the blade of a wood handled screwdriver in contact with both, while the engine is running, is a simple expedient in the absence of a switchboard or switch plugs, or, if the high tension wires to the distributor have plug joints, each wire may be detached from the distributor in turn. On tracing the faulty cylinder, begin by taking out its plug, setting the points by a gauge, if to hand, or otherwise as close as they will go without actually touching; if necessary, clean the plug head thoroughly with a knife, petrol and brush. If this do not cure, change the plug. If this do not cure, the fault will be in the wire from the distributor, provided the misfiring came on suddenly and was pronounced in character. If the miss be gradual, irregular and only faintly discernible, the fault may lie in the segment of the distributor disc which supplies current to this particular cylinder. In this case attention is best postponed till a repair shop is reached, as probably the metal segment has worn, or the insulation round it has worn, and the whole will need refacing in a lathe; but it is worth while trying to clean this portion of the distributor with emery paper or rag, and, if any metallic particles are visibly embedded in the face of the circular vulcanite recess, to scrape them off, taking care not to seriously roughen the surface (else the wiper will begin to jump).

## III.—WEAK RUNNING AND GENERAL LOSS OF POWER.

Sometimes no actual miss and no absence of the sparks can be discovered, and yet the entire engine is sluggish and difficult to start, also falling away rapidly on hills, and calling for a lower gear than formerly under accustomed circumstances. Before tampering with the magneto every precaution must be taken to insure that the fault does not really lie in the valves, carburation, etc. Where a supplementary ignition is fitted this is easily tested, as the engine will behave properly on the accumulator system. When the fault is traced to the magneto, without any possible room for doubt, it is quite an inexpensive matter to return it to the makers. They will clean it, reface all brushes and contacts, renew all weakened springs, etc., for a few shillings. But if it be preferred to tackle the matter at home, wear and resistance are the two factors to be dealt with. Wear is to be looked for chiefly in the contact breaker (vide under I), and the springs here may have lost "set." Resistance will be found wherever dirt or oil or grease exist within the magneto, particularly beneath small screwed-on parts, such as insulating washers or along shafts, or beneath brushes, and also wherever a carbon brush has been allowed to wear hard and scaly on the tip. Demagnetization of the horseshoes should never occur under two or three years of running. This job, in any

case, entails the dismounting of the entire magneto, and whoever does the work must not forget to lay a piece of iron-a couple of spanners will serve-across the horseshoe if they are detached first, or between them if the armature is taken out before the horseshoes are dismounted. On the whole, it is probably advisable to return the machine to the makers in all cases of general debility, as they will then test the entire mechanism, remedy any unsuspected derangement in the condenser, etc., and return it absolutely as good as new. However, where economy is desired, the work can be done at home; the writer has run a magneto for nearly 50,000 miles without the makers ever seeing it, and it is now as efficient as when it first left their factory. —The Autocar.

#### Motoring and Linens.

Motoring, besides having revolutionized travel, bids fair to bring about important changes in the linen manufacturing industry. Flax fabrics are now being extensively utilized for making motor cloaks, overalls, costumes, etc. Besides being largely patronized by motorists for personal wear, linen cloths are popular as material for making detachable linings for the interior of automobiles, cushion covers, head rests, etc. The advantage of these detachable linings is that, after the dust and grime of a day's travelling, the covers can, with but little labor, be taken off and washed. and the car turned out next day cool, clean and comfortable looking. In the manufacture of motoring costumes, although colored materials enjoy a certain amount of patronage, the prime favorites are cream and natural shade cloths. The weight of material varies according to individual tastes, but there is a decided preference for light-weight with a close texture. The fact that linen can be woven so close in texture is one of the chief reasons why it stands unique as an article for making motoring garments. An essential is to get something wind and dust proof, and with a compactly made flax fabric this end is accomplished better than with any other textile, excepting, of course, material subjected to a waterproofing process. Another reason why linen cloth is growing in popularity with motorists is that overalls and such like garments can be slipped off and on in an easy way without disarranging one's attire. While thousands of pieces have already been shipped this year to the United States for making motor costumes, the new business arranged with manufacturers for spring trade for 1910 is of unusual dimensions. Most of the materials utilized have been of a plain texture, but there is a growing demand for a moderate priced twill cloth, which is said to be a better protection against wind, though if twill be too coarse it serves only to hold dust and dirt. However this may be, there is no doubt that manufacturers will be able to make materials that experience may from

time to time prove to be best adapted for whatever part of the world they are required.—The Autocar.

#### German Truck Wheels Standardized.

The German Automobile Manufacturers' Association, co-operating with the German War Department, has agreed upon standard sizes for motor truck wheels and tires. It will be remembered that the German War Department pays a substantial bonus to all purchasers of motor trucks of certain types which have been found suitable for military purposes and whose purchasers pledge themselves to hold the trucks in readiness for the use of the War Department. The standards referred to were agreed upon at a meeting held at Berlin on July 1. In future all 4 ton trucks will be equipped with wheels and tires of the following dimensions: Diameter of front wheel rims. 670 mm.; width of front tires, 120 mm.; diameter of rear wheel rims, 850 mm.; width of rear tires (double), 140 mm.; diameter of front wheels with tires, 830 mm.; diameter of rear wheels with tires, 1.030 mm. A uniform method of fastening the rubber tires to the rims, known as the "slot fastening," was unanimously adopted. The advantages to the War Department of standard wheels and tires on all of the motor trucks on which it pays a bonus are obvious. It is intended to also standardize other parts of the trucks.

#### Long Stroke Motors.

The recent Prince Henry Tour in Germany furnished numerous instances of the practice among manufacturers of increasing the proportion of the stroke to the bore. The rules of the contest did not favor the long stroke motor, as the horse power was calculated by means of a formula making it proportional to the square of the bore and the two-third power of the stroke, which is thought to be in very close accordance with the actual facts. It is believed that practically all of the competing cars were stock machines, so far as cylinder dimensions are concerned. Following are some examples of long stroke motors of more or less prominent make:

Name.	Millimetres.	Inches.
Fiat	118x190	4.72 <b>x7.</b> 6
Gobron-Brillie	. 112X200	4.48x8
Austrian Daimler	115×154	4.6 x6.16
Metallurgique	. 106x171	4.24×6.84
Presto	. 100x200	4 x8
Benz	. 110X150	4.4 x6
Opel	. 110X150	4.4 x6
South German	. 100X200	4 x8
Horch	. 85x170	3.40x6.80
Mercedes	. 90X140	3.60x5.60
Laurin & Klement	. 85x150	3.4 x6
Opel (winner)	. 70X125	2.8 x5

#### New Swedish Tariff.

The Swedish Parliament has at present under discussion a revised tariff schedule which will slightly affect the importation of automobile parts and accessories. The new schedule is a very comprehensive one, comprising no less than 1,281 headings. It

is the intention to apply a single or uniform duty instead of a differential duty, as is provided for by the new American tariff. In case any foreign country should legislate against the Swedish industry, it is the intention to retaliate by adding a certain percentage to the duties upon goods imported from that country. One of the changes in the new tariff, as compared with the old one, relates to motorcycles. These will hereafter be dutiable at 60 crowns apiece, instead of at 15 per cent. ad valorem, as formerly. As the average price of a motorcycle is about 400 crowns, there is really no appreciable change in the rate of duty. Parts of motorcycles not specially enumerated will be subject to a duty of 2 crowns per kilogram, the same as bicycle parts. Wagons and vehicles not specially enumerated, also such provided with motors, as well as running gears for same, and rubber tired wheels for such vehicles. are subject to a duty of 15 per cent. This heading covers automobiles, and the rate of duty on these vehicles remains, therefore, unchanged.

## New French Road Law in Preparation.

The French Minister of Public Works, Barthou, is making arrangements for the drafting of new road traffic laws, and an international congress for the purpose of unifying road rules has been called to be held in Paris on October 5 next. The first step taken by the minister was the appointment of a committee on investigation, which held its first meeting on June 17 at the office of the Minister of Public Works under the chairmanship of General Inspector Lethier of the Department of Road Building. The committee, which counts among its members several representatives of the Touring Club of France, the Automobile Club of France and the automobile press, decided to begin its work by collecting the traffic regulations in force in the different parts of France and to make a thorough study of these regulations.

#### Pressed Steel Flooring.

The latest use to which pressed steel has been put is as a pavement or floor covering. It can naturally be used only where special conditions obtain. The subject has been taken up by the Forges de Douai of France, which produce the Arbell pressed steel used on a majority of French automobiles. One of the courts at the Douai works has been laid with this paving material or covering, and it has also been applied as floor covering in front of boilers, etc. The upper surface of the sheet is provided with diamond shaped protuberances which serve the double purpose of retaining the sheet in place and making it non-slipping. After the sheet has come out of the press, and while it is still hot, it is quenched in coal tar or oil to protect it from rusting. The sheets which have been made so far are 5-32 inch thick and 51/2 inches square, weighing a little over 3 pounds each.

## The Sixth Annual A. A. A. Tour. (Continued from page 94.)

hour more sleep. Rest, if I may say so, is one of the most desired privileges on the tour. Late to bed and early to rise is the slogan of the tourists. Few of the cars on these 200 mile runs are able to get in much before half past three or four o'clock, and many do not reach the night control before six. As a result the tourists must stay up later, and yet we all have to get up just as early in the morning.

This morning the first car started at seven, as usual, but since the watches had been set back the sun was really much higher and so the trip was made more in the heat than any day before. To add to the discomfort of the passengers in the cars the route lead through alkali plains where the hot white, penetrating dust blistered the faces and parched the lips of the travelers. As far as Fort Morgan conditions were worse than the day before, but they were not to be compared with what were met with beyond there and almost up to Denver.

After leaving Julesburg, 20 miles of good roads gave the tourists good opportunity for speeding, but these were followed by another 20 miles of newly made roads which were so rough that more than one passenger lost his patience. On this rough stretch a ford was met, the first on the tour so far, which came near stalling many of the cars., The ascent out of it was so badly cut up that the axles and pans scraped if the car got into the ruts. The writer saw the Mason, No. 112, stalled at this point. With the crews of Cars No. 1, 53, 5 and 106 to help and a good rope the car was quickly extricated. This taught the drivers a good lesson, viz., that it was bad policy to get into the ruts another fellow had made. The writer at this point observed one of the cars with both front wheels off of the ground, only the front axle holding the car. When the power was applied the car must have been pushed fully a yard while riding on the axle.

After leaving Sterling, 61.9 miles, comparatively good roads were had all the way to Fort Morgan, 112.7 miles. They were only of dirt but they were well worked and kept in fine condition. Beyond Fort Morgan the contestants first had a taste of real prairie, and few seemed to enjoy it. The 60 miles from Fort Morgan to Bennett were almost without a house. In several places it was a matter of 15 or 20 miles between houses. In addition there was not a single tree or protection from the blazing sun for the whole distance. The roads were nothing more than cow paths where there were any at all; elsewhere the confetti was our only guide. In one or two places the cars lost their way.

At one point on this trip across the prairie a bridge had to be crossed which was abominable. The approach and descent were about a foot above the ground and the whole structure was so flimsy that it is a wonder that only one car came to

grief in crossing. The Thomas press car broke through one side of the floor planking and when the following cars arrived they found hardly more than 3 inches to spare on each side of the wheels. To get the cars up onto this place, over a foot high, and not drop into this hole taxed the drivers' skill to the utmost. Besides, after each car passed it was necessary to rebuild the floor.

Several of the cars which attempted to follow in the wheel tracks along the prairie roads were nicely hung up on their rear axles and had to fill up the ruts with clay and dirt, as no stones could be found. The axles were then jacked up and the cars driven out. Some of the cars did not carry shovels or rope, and they had a bad time of it. Most of the contesting cars are carrying shovels, rope and block and tackle.

The prairie dogs which Dai H. Lewis has been promising us for some time were seen for the first time during the afternoon. All the way across the 60 mile stretch they were constantly in evidence. Also sage brush and cacti were everywhere that the eye turned.

#### STRAIN ON THE DRIVERS.

Only one car will receive a penalty of any importance today, this being the Glide, No. 10, driven by A. Y. Bartholomew. Tire troubles were few also, there being only four cases. It seems that the drivers and passengers are put to a harder test than the cars. The long hours, the excessive heat, the want of water and the treacherous condition of the roads are beginning to have their effect on them. Three days of over 200 miles' driving under such conditions comes near being the limit of human endurance, especially when the runs are under a schedule time.

Many parched and bleeding lips were to be seen on every arrival, caused by the alkali dust. To protect themselves the majority of the tourists had handkerchiefs tied across their noses and mouths. Many also provided themselves with sunbonnets to keep the sun off their faces.

#### LESSONS TAUGHT.

So far the run has been a revelation to the Easterners who have never been in the West before, and indeed also to those who have only seen it from the windows of a Pullman car. Many have expressed their surprise at the richness of the country, and the opportunity which it offers for the automobile manufacturer. This is especially the opinion of H. O. Smith, president of the Premier Company, and also Howard Marmon, of the company bearing his name. The people all along the route of the tour seem to think that there must be some obscure reason why this or that car is not on the tour. "Are they afraid of our roads?" This is one of the questions often asked. On the other hand, everyone seems to have the idea that any car which goes on this tour is all right. To appreciate this sentiment it is necessary to be with the contestants, and get in close touch with the people, so Mr. Smith said.

The Thomas No. 10 had its perfect score spoiled today when it was necessary to repair the gasoline feed pipe. Ten minutes were required to do this, and a penalty of one point was assessed.

The Glide No. 10 was late arriving, at 7:45 in the evening. The trouble was the breakage of a spring, which had to be replaced. The tardiness was 128 minutes, which will probably eliminate the chances of this car as far as winning the trophy is concerned. Mr. Bartholomew also had fan belt trouble. This makes the seventh car with fan belt trouble.

No. 105, Chalmers, driven by Jas. Machesky, shored off the magneto drive pin, and will have to continue the run with battery ignition alone.

It is also reported that the Marmon No. 5 had some trouble with the fan belt, and may receive some penalty for it.

Today saw another clean score tire record spoiled, for the Mason No. 112 had its first puncture. The only cars remaining with a perfect record in this respect are Nos. 9, 52, 53, 102 and 107. Nos. 9 and 102 have Goodrich tires, 52 and 53 have Diamonds, and 107 has Ajax.

#### ARRIVAL AT DENVER.

Scarcely had we checked in at Denver than the members of the Denver Motor Club took us to their clubhouse, which is located only a few steps from the parking enclosure, and did everything in their power to refresh the inner man. Refreshments of the sort that remove the alkali dust from the throat were served, and up to a late hour last night the tourists were still gargling their throats.

The Denver Athletic Club also opened their clubhouse to the visitors, and many took advantage of the swimming pool which it offered.

#### PROGRAM OF FESTIVITIES IN DENVER.

July 25.—10:30—Meet at the Denver Motor Club for an automobile ride over the city and suburbs, returning to the club for a buffet luncheon. 3:30—Special street cars for Lakeside, where a young couple married on the spot will start on their honeymoon in a balloon. Vaudeville and all concessions to be visited. 6:30—Banquet to the tourists.

Monday, July 26.—8:30—Special train on the Colorado and Southern over the famous Georgetown loop, and to the top of Mount McClellan. A special lunch car will accompany the train. 6:30—Open house at the Denver Motor Club; entirely informal.

## Chicago Meeting of Automobile Engineers.

Headquarters for the Chicago meeting of the Society of Automobile Engineers will be at the Illinois Athletic Club, 145 Michigan avenue. This is a private club, and it therefore becomes necessary for all those attending the meeting to become guests of one of the Chicago members, who is also a member of the club. F. J. Newman is in charge of the arrangements.

## Fairview Motor Company to Make Trucks.

There have recently been repeated signs of increasing activity in the commercial vehicle branch of the industry. In the last two issues we reported plans of extension of two commercial vehicle concerns located in Michigan, and as we go to press our Detroit representative telegraphs that a new company has just been organized there to manufacture commercial vehicles exclusively. The concern is to be known as the Fairview Motor Company, and is backed by the men who are in control of the Chalmers-Detroit Motor Company.

#### New Kinsey Company Organized.

The Kinsey Manufacturing Company, of Toledo. Ohio, which was incorporated recently, held a meeting at its office on last Wednesday, and elected the following officers: Isaac Kinsey, president and general manager: John N. Wilson, vice president and treasurer, and Homer V. Hawk, secretary. The old Kinsey Manufacturing Company was located in Dayton, Ohio, where it manufactured frames, radiators, oilers, etc. Some months ago the company sold its plant to the Dayton Motor Car Company, and removed to Toledo, where it occupied part of the former Pope Motor Car Company's plant. The new firm will engage extensively in the manufacture of automobile parts.

## Muncie Motor Truck Company Organized.

The Muncie Motor Truck Company has been organized at Muncie, Ind., and will establish a factory either in Muncie or Yorktown for making motor trucks. Interested in the company are D. O. Skillen, glass manufacturer, of Yorktown; Thomas L. and Hugh Warner, automobile parts manufacturers, of Muncie, and Milton E. Ailes, vice president of the Riggs National Bank, of Washington, D. C.

#### lowa Dealers Organize.

Dealers from all parts of Iowa met at Marshalltown on July 12, and organized the Iowa Automobile Dealers' Association. The following officers were elected: D. P. McClure, Oskaloosa, president; W. E. Sears, Des Moines, first vice president; M. J. Dannatt, Clinton, second vice president; C. C. Eldridge. Marshalltown, secretary and treasurer.

One of the grievances of the Iowa dealers is the delay in deliveries from factories and jobbers. The demand for automobiles this year has been so great that many dealers have been obliged to wait much longer for their cars than they had expected, and this, of course, entails many annoyances to them. The Marshalltown A. C., which recently promoted the organization of a State A. A., co-operated with the local dealers in entertaining the visitors. One of the features of the meeting was an automobile parade through the main streets of the city.

Another meeting will be held in Clinton at an early date. A constitution and by-laws will be adopted, and the association will incorporate. It is planned to establish a rule to allow members to sell cars outside their territory, on the condition that they turn over one half of the commission to the agent in that territory.

#### Final Report on Pope Manufacturing Company.

Counsel for receivers of the Pope Manfacturing Company has filed their final report, according to which, after paying all claims in full, with interest, there remain sufficient assets to pay a dividend of 41.277 per cent. on \$2,391,000 of first preferred stock. Vice Chancellor Howell, to whom the report was presented, has signed an order directing persons in interest to show cause next Monday why the report should not be confirmed and the receivers discharged upon the making of final distribution.

#### Trade Personals.

Mr. Derose, formerly of Aurora, Ill., has taken charge of the selling end for the Gary Motor Car Co., Muskegon, Mich.

Berry Rockwell, late of the Railway Steel Spring Co., has accepted the position of advertising manager of the Maxwell-Briscoe Motor Co.

J. B. Chapman has resigned as treasurer and general manager of the Belmont Garage Co., Washington, D. C., and has been succeeded by R. W. Nichols.

Tyrus Cobb, of Macon, Ga., has been appointed State manager for a Detroit automobile manufacturer, and will be in control of agencies at Atlanta, Savannah and two other Georgia cities.

A. L. Bolster has been appointed manager of the Philadelphia Fisk tire branch, which is located at 258 North Broad street. He succeeds K. B. Harwood, who becomes special outside factory representative of the Fisk Co.

E. Mack Morris, manager of the Model Automobile Co., Peru, Ind., was in New York recently establishing an Eastern agency for the company's Great Western cars. We are informed that Mr. Morris secured contracts for 725 cars while here.

David H. De Armond, Hamilton, Ohio, has bought the interest of Harry J. Stead in the Hamilton Automobile Co. Mr. De Armond's brother, W. R., will be the business manager of the garage in the future. The company handles the Maxwell and Overland cars.

W. N. Hellen, formerly with the Bergers Automobile Co., Omaha, Neb., has assumed the retail managership of the Velie Motor Car Co. branch in Omaha, which has recently moved to new quarters at Nineteenth and Farnam streets. Mr. Hellen will also handle the Columbus electric car.

Benj. H. Ooley has been appointed manager of the Dayton, Ohio, distributing branch for Chalmers-Detroit cars. Mr. Ooley has established a temporary office at 1004 Conover Building, but will shortly move into a salesroom in the new Bimm Building, corner of Main and First streets.

Ernest Coler has assumed charge of the Maxwell-Briscoe Motor Co.'s new publishing department. Mr. Coler, who has looked after the Maxwell's publicity for the past two years, will continue to pulish the Co-operator, and will also be responsible for most Maxwell literature.

Edwin E. Peake, of Detroit, Mich., has been appointed manager of the Regal Motor Sales Co., 758-60 Woodward avenue. The Sales Co. controls the sales of Regal cars throughout the State of Michigan. Mr. Peake was formerly connected with the sales department of the Detroit Buick branch.

#### New Incorporations.

Adams Garage Co., Trenton, N. J.—Capital stock, \$25,000.

Universal Auto Co., East Orange, N. J.—Capital stock, \$50,000. To manufacture automobiles. Colorado Auto-Lite Co., Denver, Col.—Capital stock, \$800. Incorporators, W. J. Peete, John E. Fry and J. W. Foster.

Oldberg Manufacturing Co., Detroit, Mich.— Capital stock, \$10,000. Incorporators, V. Oldberg, H. P. Wayman and A. C. Born.

Emergency Automobile Tire Co., South Bend, Ind.—Capital stock, \$25,000. Incorporators, Chas. M. Culp, Alfred J. Kroencke and Geo. C. Fish.

The Garlock Auto Specialty Co., Palmyra, N. Y. —Capital stock, \$10,000. Incorporators, Olin J. Garlock, Herman E. Whiting and Sanford D. Van Alstyne.

The Albany & Berne Auto Co., Albany, N. Y.—Capital stock, \$20,000. Incorporators, Frank Tompkins, White Plains; Henry Binns, W. T. Cheseboro, of Berne; T. N. Renny, of New York, and R. D. Fowler, of Singerlands.

#### New Agencies.

Atlanta, Ga.—Georgia Motor Car Co. Columbus, Ohio.—A. J. Pray, Studebaker. Heppinger, N. D. -A. R. Castle, Overland, Louisville, Ky.—George Looms, Locomobile. Grand Rapids, Mich.—M. L. Hughes, R. & L. St. Louis, Mo.—The Park Automobile Co., Hud-

Portland, Me.—Harmon Automobile Co., Hud-

Houston, Tex.—Cotton & Dupuy, Babcock electric.

St. Louis, Mo.—Brenton G. Van Cleave, Speed-

Milwaukee, Wis.—Edgar F. Sanger Co., Oldsmobile.

Salt Lake City, Utah.—Botterill Automobile Co., Hudson.

#### MINOR MENTION

The Imperial Automobile Company, Jackson, Mich., are to bring out two models.

The Fuller Buggy Company, Jackson, Mich., will put out a pneumatic tired machine this fall.

E. D. Carlough, Paterson, N. J., who has secured the State agency for the Autocar for 1910, will shortly open a branch in Newark.

The Badger Automobile Company, of Columbus, Wis., has purchased a tract of 20 acres in the city of Columbus, and will begin the erection of shops at once.

R. E. Smith plans to establish an automobile supply store in Sherman, Tex., and would like to hear from manufacturers and jobbers wishing to be represented there.

The Auto-Bug Company, of Norwalk, Ohio, has recently completed a new model, known as Model E, a five passenger, two cylinder, 22-24 horse power car.

The Auto Go-Cart Company, of Beloit, Wis., will shortly remove to Monroe, Wis., and increase its capital from \$25,000 to \$50.000. The company is being promoted by Sam Kneller and Fred Koplain.

The hill climb which was to be held at Richfield Springs, N. Y., on July 31, has been postponed until August 7, on account of interference of the date with that of the Brighton Beach twenty-four hour race.

The American Motor Car Sales Company's Eastern office has been moved to 1776 Broadway, New York. The office is in charge of Thomas Forbes, and American and Pope-Toledo cars are sold from it.

Thomas B. Jeffery & Co. inform us that up to June 1, 1909, 7,383 cars had been registered in Wisconsin. of which, the largest number of a single make, 733 were Ramblers. This make, they say, also leads in Illinois.

For the month ending July 15, \$21,129 was collected by the Motor Vehicle Department of Ohio as fees for 1,775 registrations by owners and twenty-five by manufacturers. The total receipts from the registration of automobiles and licensing of operators for the year ending June 10 was \$120,101.23.

The Kansas City Chauffeurs' Club, which has its headquarters at 1735-37 Grand avenue, and boasts of a membership of more than 100, has arranged for weekly lectures by local dealers and others. The first lecture was given on July 22 by Chas. V. Fyke, local representative for the Locomobile.

The Licensed Chauffeurs' Protective Association of the City of New York was incorporated last week by Mathew J. Gonnoud. 1595 Lexington avenue; Frederick Walter, 1600 Lexington avenue, and Isador Klatzke, 133 East 104th street. One of the objects of the organization is to furnish bondsmen for members who may be arrest-

ed in the lawful pursuit of their calling, and counsel to defend accused members without cost.

The Buffalo Carburetor Company, Detroit, Mich., are breaking ground for a foundry, which will be one of the best in the State.

An automobile mart, consisting of a six or seven story fireproof building, is to be erected in Newark, N. J., somewhere near the centre of the city. The building is to be let exclusively to dealers in automobiles and accessories.

The Perry Tire Protective Company, of Lansing, Mich., has been bought by the Union Steel Spring Company, of Albion, Mich., and will be removed to the latter city. The Perry tire protector is a chain anti-skidding device.

A convention of branch managers of the Ajax-Grieb Rubber Company will be held at the factory of the company in Trenton, N. J., July 28-31. A number of the Western branch managers are now en route to the East to attend the convention.

A Minneapolis inventor has applied for a patent on a new double inner tube. It comprises two separate chambers formed by a partition, with a valve opening into each, so that either chamber can be used. If one chamber is punctured the other one is inflated.

The Grabowsky Power Wagon Company, of Detroit, Mich., have recently sold the remainder of their treasury stock, and all of the \$300,000 stock has now been placed. The money obtained from the recent sale will be used for the erection of an additional factory building.

The Indiana Automobile Parts Company has been organized at Marion, Ind., by Geo. R. Stewart, president of the Indiana Brass and Bronze Company, and several others. The new company will absorb the Indiana Brass and Bronze Company, and will manufacture a line of automobile parts.

John F. Baker, trustee of the bankrupt estate of Thos. D. Buick, Flint, Mich., has made application to the courts to sell the remainder of the assets at public auction in the store of the bankrupt on July 31 at 10 a. m. A hearing will be given to creditors on this matter at the office of Wm. R. Franklin, Flint, Mich., one hour before the time set for the sale.

The George H. Gibson Company, Tribune Building. New York city, has taken the American agency for the *Technical Index*, a monthly paper published in Brussels, Belgium, giving a systematic descriptive record of all original articles appearing in over 200 engineering and technical journals and reviews, and indexing the proceedings of technical societies.

The Wordingham Manufacturing Company has been incorporated, with a capital stock of \$50,000, to manufacture a foot horn and other accessories and specialties for motor cars. The incorporators are W. G. Wordingham, Phil Kennedy and W. R. Greenlaw. The foot horn is the invention of Mr. Wordingham, and was exhibited at

the Milwaukee show last March. Quarters have been leased, but it is planned to eventually build a factory.

The Universal Motor Company, of Denver, Col., which has brought out a combination gasoline-electric vehicle system, is trying to interest Lansing, Mich., capitalists in a factory for the manufacture of trucks under this system in that city. Each wheel of the truck is provided with an electric motor, and the current is furnished by a gasoline engine driven generator carried on the vehicle.

#### Club Notes.

The Ontario Motor League has had prepared a summary of the motor vehicle laws in effect in the different sections of the Dominion of Canada.

The Cincinnati A. C., whose constitution limits the active membership to 500, now has reached that mark, and plans to amend its constitution to remove the limit.

The Cloud County (Kan.) A. C. is being organized by L. F. Davidson, and will probably have its headquarters at Concordia. It is planned to hold a number of road contests during the season.

The Duluth (Minn.) Automobile Club is to be reorganized, and a meeting for the purpose was held at the Commercial Club on July 15. The old officers of the club have resigned, and new ones are to be elected.

The Augusta (Ga.) A. C. has adopted resolutions protesting against an automobile tax bill, which is to be introduced in the State Legislature during the next few days. A copy of the resolutions was sent to Senator W. S. Morris.

The Winnipeg (Man.) A. C. is arranging for an automobile tour from that city to Minneapolis, Minn. a distance of over 1.500 miles. The tour will pass through Moose-jaw (Sask.), Devil's Lake, N. Dak.; Jamestown, Fargo, Detroit Lakes and Grand Forks.

The Floyd County (Ga.) Automobile Association was organized at Rome on July 16, with twenty-six charter members. The following officers were elected: A. N. Tumlin, president; Fred Hanson and Wm. De-Lay, vice presidents; W. B. Shaw, secretary and treasurer.

The Peninsula Automobile Association was organized with thirty-nine charter members at Newport News, Va., the past week. The following officers were elected: W. A. Post, president; L. B. Manville, vice president; W. L. Cooke, secretary-treasurer, and E. B. Dennie, assistant secretary-treasurer.

The Milwaukee Automobile Club will meet in special session on Thursday night, July 20, to make a final decision in the matter of building a clubhouse. There has been some difficulty in obtaining an expression of sentiment as to the advisability of mortgaging the club's present properties to cover the cost of a building, but proxies will be legal at this meeting, and the vote will be

final. The club owns a 5 acre tract at Blue Mound and Cottrill avenues, west of Milwaukee, and will have one of the finest club properties in the West if the vote is in favor of building, which is wholly probable. The clubhouse would cost \$12,000.

Garage Notes.

The Beatrice (Neb.) Automobile Co. has let contracts for a \$5,000 brick garage on Fourth street.

J. C. Blackburn, Omaha, Neb., recently completed a new garage and implement building, 26x140 feet.

The Utica Automobile Co., Utica, Neb., have begun work on a new store building, 16x32 feet, near their garage.

The Ashtabula Garage has been opened at 44 Centre street, Ashtabula, Ohio, with George H. Holmes as manager.

Work has been begun on the garage of J. H. Donner, of Aurora, Neb. The building will be 40x60 feet, of brick veneer.

The C. A. Shaler Co., of Waupun, Wis., who manufacture the Shaler vulcanizer, is handling the Elmore line in Wisconsin.

The Minneapolis branch of the Studebaker Automobile Co. has decided upon a site at Sixth street and Second avenue for its seven story warehouse.

The Bruening Brothers Automobile Co., Kansas City, Mo., have removed their garage to their new building on Armour and Broadway boulevard

A building on Jefferson avenue, Detroit, near Woodward avenue, is being remodeled for the Cunningham Auto Co. The new company will sell E-M-F and Studebarker cars.

The Central Garage has been opened in Flint, Mich., in the Watson Block, corner South Saginaw and East Court streets. A specialty will be made of repair work. J. W. Barton is proprietor.

V. S. Darling, Auburn, Me., has leased the store in the new National Shoe and Leather Bank Building, in which he will conduct his supply business and agency for the Maxwell and Rec cars.

Dr. H. A. Lawton, Cleveland, Ohio, has taken the local agency for the Waverley Automobile Co., and has taken space at the garage of the Elmore Motor Car Co. at East Nineteenth street and Euclid avenue.

The Reliance Automobile Co., of San Francisco, Cal., has recently moved to its new sales-room on Van Ness avenue. The shop and garage of the company will remain at the old location in Fulton street.

The Central Motor Car Co., Oklahoma City, Okla., are fitting up a repair shop in the Crowder Building on California avenue, and are negotiating for a new 50x140 feet building for a storage and salesroom.

The Western Automobile Co., of St. Louis, Mo., has taken a ninety-nine year lease on a property at the corner of Washington avenue, Olive street and Walton avenue. The company will erect a modern garage on the site, provided a bill now pending in the Legislature is passed.

Herman Schnure, secretary and manager of the Van Automobile Co., St. Louis, Mo., has resigned from that company, and will open a new business at 1131 Olive street about Apgust 1. Mr. Schnure recently returned from Detroit, where, it is understood, he secured a number of agency contracts.

W. A. Voigt and Albert Maurer, of Sheboygan, Wis., and Fred C. Voight, of Milwaukee, Wis., have purchased a building site at 816 Niagara avenue, Sheboygan, and will erect a large garage. Plans are for a two story, reinforced concrete building, 60x100 feet in size. The location is in the centre of the business district, near the largest hotel in the city. The repair department will occupy part of the first floor and the basement.

The Cubbins Automobile Co., Mcmphis, Tenn., composed of John F. Cubbins and Malcolm M. McCallum, has leased a building at 187 Court avenue, which it will fit up as a salesroom. The company has taken the agency for the Brush

runabout, and expects to take on several other lines.

The United Motor Co., Wichita, Kan., has moved from 115-119 East Second street to its new store at 114 North Emporia avenue.

C. E. Cain & Son, of Waupaca, Wis., have opened their new garage and machine shop, and are also handling accessories and specialties.

Thieves broke into the garage of D. F. Maltby at Glen Cove, L. I., on the morning of July 25, and stole tire covers, tools, etc., valued at \$700.

The Buick Motor Co., New York branch, is now occupying the entire building at Broadway and Sixty-fifth street, which it formerly divided with the Lozier Motor Co. and the Auto Supply Co.

The B. L. Huffman Automobile Co., Omaha, Neb., have moved from Nineteenth and Farnam streets to the former quarters of the Coit Automobile Co. at 2025 Farnam street, The Huffman Co. handles the Interstate and Hupmobile.

A building is being erected on the north side of Farnam street, Omaha, Neb., for use by the Electric Garage Co. It has a frontage of 66 feet and a depth of 125 feet. Three lines of electrics will be handled, viz., the Baker, the Rauch & Lang and the Detroit.

and the Detroit.

The Fred J. Titus Automobile Co., now located at 213 Clinton avenue, Newark, N. J., will shortly move to a new building on Branford place, corner of Halsey street. The company now handles the Herreshoff and Houpt cars, and will add the Palmer & Singer line.

A plan is on foot in Mount Pleasant, Ia., to organize a garage company on the co-operative plan. It is the intention to incorporate the company, and to elect a board of directors, who will then elect a manager. A meeting for the purpose of organizing was held at the office of Chas. A. Gregg on July 13.

A three story building is being ereceted for the Baker Electric Vehicle Co. on a 50x162 feet plot at 2313-15 Michigan avenue, Chicago, Ill. The building has been leased for ten years by the Baker Company at 5 per cent. on \$55,000 for the land, and 8 per cent. on the cost of the building, which is estimated at \$30,000.

The private garage of P. Welch at 321 Eighth avenue, Spokane, Wash., was destroyed by fire on July 2, and two automobiles, two carriages and sundry equipment were also wrecked. The total loss is estimated at \$15,000, of which little is covered by insurance. It is believed that the fire was caused by short circuiting of the electric wires.

Glenn Frazell, of Springfield, Mass., has recently purchased the old skating rink in that city, which he has remodeled and fitted up as an up to date garage, and opened as the Springfield Garage. The building is located at the corner of Limestone and Mulberry streets. Mr. Frazell has secured the agency for the Studebaker and E-M-F

The E. W. Robbins Automobile Co. has been organized at Owosso, Mich., to conduct the garage now operated by W. H. Rust on South Washington street. The new company consists of J. H., B. P. and E. W. Robbins. The latter, who will have the active management of the business, up to a year ago handled the Jackson car in Los Angeles, Col.

Chas. E. Riess, of the Overland Motor Car Co. of New Jersey, has secured in addition to the New Jersey territory the Overland agency in New York for 1910. Mr. Riess will maintain a salesroom at Broadway and Fifty-seventh street, which he will manage himself, while the East Orange and Newark branches will be in charge of George Riess.

The Coit Automobile Co. and the Guy L. Smith Automobile Co., of Omaha, Neb., have recently moved into a new building on Farnam street, near Twenty-third. The building has a frontage of 72 feet and extends back 166 feet. The Smith Co. will have 48 feet frontage and the Coit Co. the remainder. The former handles the Peerless and Franklin and the latter the Rambler and Mitchell.

The Jamestown (N. Y.) Garage Co. has been reorganized. Morris Rosenbloom, a Rochester jeweler, has become president, and Benj. L. Arn-

son, of Jamestown, secretary and treasurer. The company's garage on West Second and Cherry streets will be thoroughly modernized, and a number of different makes of cars will be handled. John Down will be general manager, and Samuel Robbins, assistant manager.

A branch salesroom for Cadillac cars has been opened in Newark, N. J., at 226 Halsey street, in charge of Clarence E. Fisher, who was formerly sales agent for the Motor Car Co. of New Jersey, which formerly held the Cadillac agency. It is understood that the Detroit Cadillac Motor Car Co., which controls the branch, plans to erect a new garage and salesroom at an early date, but no site has as yet been selected.

The Nebraska Buick Motor Co. is being organized in Omaha to handle the Buick line in that State. The Bergers Automobile Co., which now handles the Buick, will confine itself to the E-M-F. after July 31. The incorporators of the new firm are: R. H. Collins, who is now general manager of the Buick agency at Kansas City; Chas. Stewart, of Madison, Neb., and J. H. Sidles, of the Sidles Automobile Co., of Lincoln. Neb.

A. A. Auble, Jr., and Fred Wood, proprietors of the Akron (Ohio) Auto Garage, have purchased the Cleveland branch of the Olds Motor Works, and will hereafter control the sales of Oldsmobile and Oakland cars throughout the State of Ohio. The new company, which will operate a salesroom at 1926 Euclid avenue and a repair shop in East Twelfth street, Cleveland, is to be known as the Olds-Oakland Co. The business in Akron will be continued.

#### Trade Literature Received.

The Simms Manufacturing Co., Ltd., London, Eng.—Catalogue of Simms motors.

The Fisk Rubber Co., Chicopee Falls, Mass.—Booklet relating to Fisk removable rims.

The Dow Rim Co., 1783 Broadway, New York.

—Catalogue of the Dow remountable rim.

Lavalette & Co., 112-114 West Forty-second Street, New York City.—Circulars regarding the Fisemann high tension magneto system.

Gray Brothers, 1111-1115 West Eleventh Street, Cleveland, Ohio.—Net price catalogue of motor car supplies.

Avery Co., Peoria, Ill.—"The Avery Farm and City Tractor."

Peerless Motor Car Co., Quincy Avenue and East Ninety-third Street, Cleveland, Ohio.—Advance catalogue of Peerless 1910 cars.

Hoyt Electrical Instrument Works, Penacook,

Hoyt Electrical Instrument Works. Penacook, N. H.—Circular describing the Hoyt Tribune voltammeter and its use for testing coils and batteries.

The White Co. Touring Bureau. 1402 Broadway. New York City.—White Route Book, No. 8, describing a route from New York city to Atlanta. Ga.

Apple Electric Co., Dayton, Ohio.—Circular describing the "Apleo" electric lighting system for automobiles.

II. H. Franklin Manufacturing Co., Syracuse, N. Y.—The Franklin Tourist Book. A book intended to help owners of Franklin cars wishing to start on a tour.

Builders Iron Foundry, 9 Codding Street, Providence, R. I.—Reprint from the Journal of the American Society of Mechanical Engineers of a paper on the Kenerson transmission dynamometer.

Detroit Wire Spring Co., Twenty-first and Standish Streets, Detroit, Mich.—Catalogue of Reliance cushion springs, Royal Arch cushion springs, New Departure cushion springs and Plain Construction cushion springs.

#### Front Springs.

Front springs, to preserve proper resiliency, should not be thicker than their width; should be fairly stiff, with a maximum deflection of not over one-quarter of an inch per hundred pounds; not off centred; and have the front eye set higher than the rear eye, not less than one-half inch, this latter preventing the car from ducking, says a bulletin of the A. L. A. M.

NUMBER 5

#### Calibrated Carburetors.

BY FRANK H. BALL AND FRED O. BALL.

Something more than a year ago an il-Justrated article appeared in THE Horse-LESS AGE, describing a series of carburetor tests in which the performance of several types of carburetors was graphi-cally shown. These diagrams represented the explosive value of the mixture under various conditions as indicated either by the pressure developed in an enclosed chamber or by the power obtained by its use in an engine in the usual manner. These tests furnished much valuable information, but they did not cover every phase of the subject as fully as might have been desired. For instance, no information was given as to the throttling resistance at full power, which is an important matter when comparing carburetor performance. Neither was the information very definite regarding the practical limits in the matter of minimum engine speed. This could not well have been otherwise, because the only definite and reasonable basis of comparison is in regard to the minimum quantity of air per minute that can be probably enriched. Because of these unanswered questions, it was thought best to take up the subject again on a more comprehensive plan. To do this a testing outfit was developed which consists of the following elements:

#### TESTING OUTFIT.

First.—An air exhausting outfit was constructed and arranged to draw air through a carburetor in any desired quantity up to the maximum capacity of the carburetor to be tested, and to do this against a choking resistance in the carburetor considerably in excess of what would be permissible in practice.

Second.—An air metering equipment was provided having a capacity greater than that of the largest carburetor to be tested, and arranged to meter with great accuracy the volume of air used under all conditions.

Third.—A water column gauge was connected to the mixing chamber of the carburetor just below the throttle, where the air and gasoline meet, and with this gauge the choking or throttling resistance of the carburetor could be noted at all times.

Fourth.—A calibrated measuring outfit was attached to the gasoline supply and arranged to measure very accurately the gasoline used by the carburetor.

With intelligent use of this equipment every important question regarding the performance of a carburetor may be answered. The measuring of the air and gasoline under all conditions shows exactly the quality of the mixture throughout the entire range of operation, and the readings of the water column gauge show the throttling resistance at all times. The practical working of this outfit in the investigation of a carburetor is shown in the diagrams that follow, each of which is a condensed summary of all the measurements obtained in a complete test.

#### BASIS OF COMPARISON.

Inasmuch as the several types of carburetors which produce these diagrams were of the same nominal capacity, it is convenient to make the comparison on the basis of the number of cubic feet of air per minute. It has been assumed in every case that 120 cubic feet of air per minute is the full capacity of a 11/2 inch carburetor; therefore the range of comparison is between 120 feet per minute and the smallest amount of air that can be properly enriched as indicated by the scale at the bottom of the charts. The vertical scale shows the number of ounces of gasoline per hundred cubic feet of air at each point of the full range of capacity. The volume of air per minute is indicated by the horizontal scale. The gasoline curve is therefore a gauge of the quality of the mixture throughout the whole range of capacity.

CARBURETOR WITH AUTOMATIC SUPPLEMENT-ARY AIR VALVE.

Fig. 1 is a complete showing of the performance of a well known carburetor of the conventional type in which the supplemental air supply is controlled by a spring opposed valve.

To understand the diagram it is necessary to keep in mind that about 5 ounces of gasoline per hundred cubic feet of air is the best mixture. It must also be remembered that the margin below 5 ounces of gasoline is very small, but that a very great excess of gasoline may pass through the engine without making the explosions cease, so that when a carburetor does not furnish a mixture of uniform quality it always means that the inequalities are in the nature of floods of gasoline under some conditions that heat and foul the engine and detract from its power.

Referring to Fig 1, it will be seen that the minimum quantity of air that can be enriched so as to be an explosive mixture is about 10 feet per minute, so that the total range of this carburetor is about 12 to 1 (assuming 120 feet per minute to be the uniform maximum for the proposed comparison of the several types).

It will also be noted that the throttling resistance at 120 feet is 23 inches of water.

In considering the quality of the mixture it will be noticed that, beginning with the smallest quantity of air that can be properly enriched, and progressing toward the full capacity, the supply of gasoline first becomes too great, the excess amounting to 56 per cent. at the maximum, and gradually decreasing as the volume of air increases until a normal mixture is reached at about the full capacity. This is a characteristic diagram of this type of carburetor, although the degree of error varies in different cases. It might be said, however, that

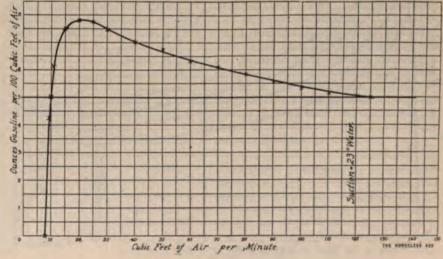

Fig. I.

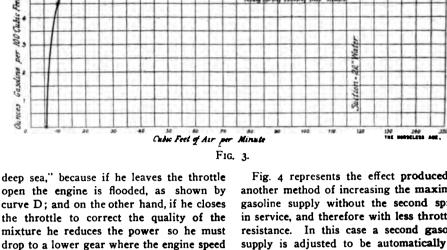

this is not an exaggerated case by any means.

To correct this apparently inherent error of performance various devices have been applied as supplemental attachments.

One method is to provide a mechanical connection between the throttle lever and the needle valve by which the quality of the mixture is changed by the movement of the throttle.

### CARBURETOR WITH INTERCONNECTED THROTTLE AND GASOLINE VALVES.

Fig. 2 is a diagram produced by a carburetor of the type just described. In this case a relatively weak spring is used on the air valve, and the mechanical movement of the needle valve is depended on to get the necessary gasoline for full capacity. The mechanical control attachment is therefore for the purpose of making it possible to use this weak spring, and thus keep down the throttling resistance. The several curves, A, B, C, D, show the gasoline supply per 100 cubic feet of air, with the throttle lever standing in four different positions. It will be noticed that the characteristic of all these curves is similar to the curve of Fig. 1, although somewhat exaggerated, and the carburetor would be impracticable except as the quality of the mixture is constantly corrected by the motion of the throttle valve. Thus with the throttle nearly closed the quality of the mixture is shown by curve A. The quality of mixture with this curve becomes rapidly too lean, but the progressive opening of the throttle valve increases the gasoline supply until finally at full speed, with throttle wide open, if 120 feet of air per minute is being used, the quality of the mixture becomes normal, as shown by curve D. It will thus be seen that the quality of the mixture depends greatly on the skill with which the throttle is handled. In climbing hills, however, conditions are met where skill does not avail much, for when the engine slows down, with the throttle open, the driver finds himself "between the devil and the

deep sea, because it he leaves the throttle open the engine is flooded, as shown by curve D; and on the other hand, if he closes the throttle to correct the quality of the mixture he reduces the power so he must drop to a lower gear where the engine speed can be maintained. It will be seen by referring to curve D that a drop of speed that reduces the quantity of air from 120 feet to 60 feet also increases the gasoline ratio about 30 per cent., and at 20 feet per minute the excess is 80 per cent.

#### CARBURETOR WITH TWO INDEPENDENTLY AD-JUSTABLE SPRINGS.

Figs. 3 and 4 are diagrams from another type of carburetor in which an automatic method of increasing the gasoline supply for full power is provided. In this carburetor the usual air valve is controlled by two independently adjustable springs. One of these is always in control of the valve, and the other is intended to engage the valve when nearly the maximum power is being developed, and by its increased resistance the gasoline supply is increased.

Thus in Fig. 3 the second spring is adjusted to engage the valve when about 77 feet of air is being used, and above that the gasoline supply is increased, as shown. The throttling resistance of this arrangement, when adjusted as shown, is 22 inches of water at 120 feet of air per minute.

Fig. 4 represents the effect produced by another method of increasing the maximum gasoline supply without the second spring in service, and therefore with less throttling resistance. In this case a second gasoline supply is adjusted to be automatically introduced at a point where about 92 feet of air is being used. The result is a great excess of gasoline, as shown, but the maximum throttling resistance is only 20 inches of water against 22 when the second spring is used instead.

It will be noted that the mimimum capacity is unchanged by any of the combinations, and remains constantly at about 10 feet of air per minute, thus giving the carburctor a working range of 12 to 1.

It would seem that the great excess of gasoline of Diagram 4 is more objectionable than an increased throttling resistance, and particularly so in this case, because it occurs at a time when the best mixture for maximum power is desired, and when unnecessary heating of the engine is fatal.

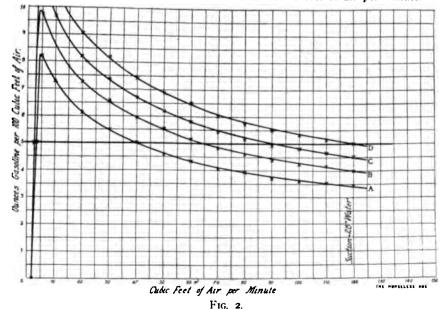

The foregoing fairly represents the performance of the several types of carburetors described, and also the effect of the peculiar features of each type. In each case a carburetor has been selected which is the product of the best known manufacturers, and those which are most extensively used.

#### THE PERFECT CURVE.

It has already been explained in connection with the several figures that a perfect gasoline curve should be a horizontal line across the centre of the sheet showing about 5 ounces of gasoline per 100 cubic feet of air at all times and under all conditions. It is proposed to show that practically this result may be obtained with a properly designed carburetor of the simplest construction without any supplementary attachments whatever.

It is unnecessary in this connection to describe this carburetor in detail further than to say that the quality of the mixture is automatically controlled by the air valve which is under the control of a single calibrated non-adjustable spring. No adjustments are provided except against the gasoline supply valve and an adjustment for correcting the gasoline level.

Fig. 5 is a diagram of the performance of a carburetor of this type. It will be seen that the minimum capacity of this car-

buretor is 2 feet of air per minute against 10, 3 and 10 feet respectively in the three types represented in the former diagrams, and the range of capacity is 60 to 1, as against 12, 40 and 12 in the former cases. It will be noticed also that at no point in the whole range is there an error in the quality of the mixture greater than 3 per cent.

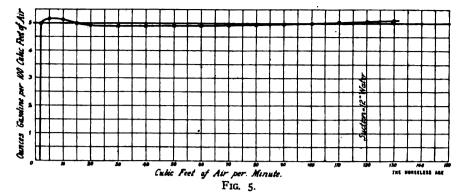

In comparing the throttling resistance a maximum equal to 12 inches of water is indicated, as against 23, 28 and 22 in the former cases. These astonishing differences can only be explained by assuming that carburetors heretofore have not been as scientifically designed as they should have been and in many cases have been "made to sell."

At the threshold of a scientific investigation of carburetors it will be discovered that the ability to give accurate performance with extremely small quantities of air is very important. In Fig. 5 the minimum capacity is 2 feet per minute, which makes it possible to have a very low maximum resistance.

A small minimum capacity necessarily implies a small regulating force in the air current, and therefore an air valve of considerable area must be used. An examination of the area of air valves commonly found in carburetors makes it evident that they never were expected to respond to small pressures. Furthermore, the resistance of the spring that opposes the valve must be exactly the right amount at every position of the valve, or the quantity of air admitted will not be in proportion to the gasoline supply. This means that the spring requirements must be definitely known and every spring calibrated and proved to be right. If a spring is not right there is small chance of making it so by adjustments. Even if an adjustment is found which seems to give good results there is no possibility of obtaining a wide range of correct performance with an adjusted spring.

#### LEVEL IN SPRAY NOZZLE.

Passing now to the consideration of gasoline supply, the absolute necessity of a constant level at the spray nozzle does not seem to have been realized. Otherwise no one would build a carburetor in which the

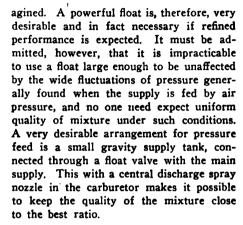

level at the spray nozzle is changed when a horizontal position of the carburetor is not maintained. The importance of the matter will be better understood by a reference to Fig. 6. Here the effect of a change of level of one-eighth of an inch is graphically shown. It will be noticed that so small a change of level as one-eighth of an inch changes the ratio of gasoline to air about 20 per cent. when 5 feet of air is being used per minute, and even when using 15 feet per minute the curve of gasoline ratio is about 15 per cent. in error.

The maximum effect of a change of level is felt at the minimum capacity as shown in Fig. 6, therefore a carburetor with a fluctuating level is not one that will give uniformly good results at very slow speeds.

To insure a constant gasoline level even with a central discharge, it is desirable to have a powerful float equipment, not only to overcome friction of the moving parts and insure quick response to small changes of level, but also to minimize the disturbing effect of varying pressures from the tank exerted under the float valve.

The displacement area of an ordinary float for a 1½ inch carburetor is 3 inches, and a tank pressure due to one foot of head exerted to open the float valve will balance a float resistance equal to one-sixteenth of an inch change of level in the float chamber.

Referring to Fig. 6, the effect of such a change of level will be appreciated. It is evident, then, that with a float capacity such as is ordinarily used the quality of the mixture follows the gasoline pressure from the tank more than would be im-

#### SUMMARY.

Reviewing the whole subject, it is evident that the following conditions must all be found in a carburetor if any refinement of performance is expected:

First.—The air valve must have area enough to insure prompt and accurate response to small changes of pressure.

Second.—The spring which controls the air valve must be exactly suited to the service both in regard to initial length and also its scale of resistance, and should not be adjustable.

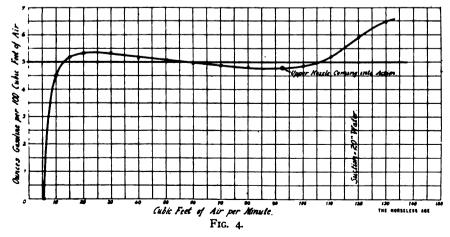

Third.—The gasoline level must not vary appreciably at the spray nozzle.

Delicacy of action in all these things does not imply a delicate and easily deranged mechanism, but, on the contrary, the result can only be realized by a rugged mechanism with power to overcome small obstacles and perform the desired functions with accuracy and certainty.

It is hardly necessary to say further, in view of the facts set forth in Fig. 2, that for the varying requirements of automobile service it is impossible to get uniform quality of mixture with any form of mechanical control, and generally a very low mileage is found with the arrangement, because of the flooding that occurs under certain conditions.

It is a self evident proposition, also, that a multiplicity of adjustments is undesirable and unnecessary, and their presence in a carburetor would seem to indicate that the builder was not quite sure what was wanted, but hoped the user would be able to work out a successful combination.

What would be said of a watch with numerous adjustments for patching up the

varying performance at different hours of the day?

A carburetor is a fairly parallel case, and if properly designed and calibrated so as to give a uniform quality of mixture throughout its whole working range the effect of a single regulating valve is to make the uniform quality richer or leaner, just as the single regulating lever of a watch makes the uniform speed faster or slower.

This gasoline regulating valve would not be necessary except for the fact that with very low barometer, as in high altitudes, the rarefied air contains less oxygen per cubic foot, and hence a relatively smaller amount of gasoline is required. This regulating valve should be the only adjustment on a carburetor, except one for correcting the level in the float chamber, the importance of which is shown in Fig. 6, and to do this conveniently the level should be visible.

ADJUSTMENT BY ENGINE SPEED CRUDE.

Nothing is more certain than that a carburetor carefully calibrated with a metering outfit cannot be improved by any subsequent adjustment on an engine. The method of "feeling" for the right mixture by observing the performance of an engine is exceedingly crude. A fair idea of the lean edge of the mixture may be obtained in this way, but the rich side is a wide open field into which the bad performance of imperfect carburetors dumps the wasted gasoline with little evidence of the fault. This fact becomes very apparent in testing carburetors taken from cars where they were supposed to have been doing good work. Fig. 2 illustrates a case of this kind. The carburetor making this diagram was first tested just as it had been used, but the diagram was so very poor that it was really "not fit for publication." The adjustments were then changed and the spring cut off and made shorter, and finally Fig. 2 was produced as the best possible performance when adjusted with a metering outfit.

The limitations of a magazine article prevent going into these subjects more fully, and it has only been possible to give rather briefly some of the most important facts that are made so very plain with a metering

testing outfit. No one could go through such tests as have been described, with the opportunity of checking the results with actual service on an engine, without being impressed with the crudeness of the usual method of engine testing as a means of developing and adjusting carburetors.

The conclusion is inevitable that the day of this sort of thing is over, and hereafter carburetors will be made on scientific lines and calibrated with a metering outfit, which will insure the same exactness of performance that is obtained with numberless other instruments of precision.

lt may be stated, too, without fear of successful contradiction, that it is now demonstrated to be practicable, both commercially and as an engineering problem. to design and build calibrated carburetors whose performance is so exact that the greatest error is a negligible quantity. This means that the mechanical control, the adjustable spring and the side float chamber must be abandoned, and an increasing number of users of carburetors will hereafter require guaranteed performance in regard to the maximum choking resistance, the range of working capacity and the amount of variation from a uniform quality of mixture throughout this range.

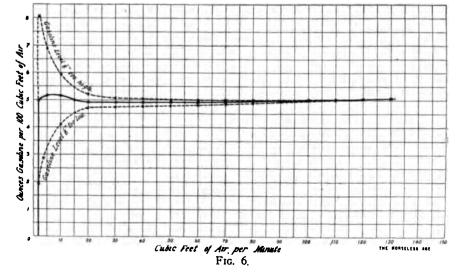

#### Piston Head Thickness.

BY F. E. WATTS.

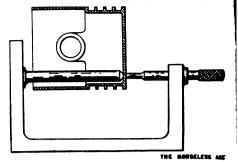

Several cases where pistons have failed owing to thin spots in their heads have come under my observation during the past year. It would seem that these annoying occurrences might be absolutely prevented by the inspection of these heads for thickness at various points. This might be done by a gauge similar to that shown in the sketch. The plunger would need only two graduations, one for the greatest and one for the least thickness allowable.

With some methods of chucking the thickness of the piston heads are automatically gauged, but even if this is the case an inspection is advisable if the pistons are of large diameter.

Similar methods might be applied to the inspection of cylinders, for cases have come

up within recent years where a lot of castings having the cores slightly too long have

PISTON HEAD GAUGE.

cost the engine manufacturer several hundred dollars, for the engines were placed in cars, and some of them shipped to owners before the heads began to break.

#### Popping in the Carburetor.

Novices in the use of gasoline motors are often puzzled and annoved by what is variously known as carburetor explosion, back explosion or popping in the carburetor. This is one of the easiest things to explain and remedy of any that may happen to a gasoline motor. The direct cause of the popping noise is an ignition of the gases in the inlet pipe and carburetor during a suction stroke of the motor. The gases are ignited by a flame in the cylinder after the inlet valve opens, left over from the previous explosion or power stroke Ordinarily combustion in the cylinder ceases soon after the exhaust valve opens if not before, but when the mixture furnished by the carburetor is very lean-that is, when it contains too small a proportion of gasoline-it is very slow burning, and the remanent gases which remain in the cylinder at the end of the exhaust strok: still continue to burn. As soon as the inlet valve opens these slowly burning gases come in contact with the new charge enter ing the cylinder and cause the explosion of the charge in the inlet pipe and carburetor.

The "leanness" of the mixture may be due to improper adjustment of the gasoline needle valve. Often carburetor explosions occur when the supply of fuel in the tank has become exhausted and the level in the float chamber and spray nozzle gets low in consequence. Another possible cause of lean mixture is loosening of the spring on the supplementary air valve, which causes this valve to open too far for any given motor suction, thus diluting the mixture too much with air.

It is a good idea when instructing a novice in the operation of a gasoline motor to bring about popping in the carburetor artificially, and to explain it to him.

The Paris Automobile Show for 1909 has finally been definitely abandoned. The committee of the A. C. of France decided to bow to the desire of the Manufacturers' Association, and to postpone the show until next year.

Cable: "Horseless." New York and London, Western Union Code.

#### The Glidden Tour.

In a recent editorial we pointed out that the Glidden Tour would be a very severe test, and that only the most substantially built cars could be expected to go through with a chance for the prizes. From the entries made it seemed that not all of the manufacturers agreed with us, but even the first few days proved our view to be correct. We have always believed that in order to make an average speed of about 20 miles per hour over ordinary country roads for many days in succession a car is required not too light, thoroughly well proportioned, and equipped with good flexible springs and liberal sized pneumatic tires. Such a speed is beyond the practical limit of solid tires. It must, of course, be remembered that an average of 20 miles per hour involves much higher temporary speeds.

It is no discredit to the small, low priced cars that they could not keep up this pace. The man who wants to drive at such speeds over country roads "has no business" buying a car in the \$1,000 class. High

speed is expensive, and the present tour has again shown that one of the chief differences between high priced and low priced cars is that the former are able to maintain a higher average speed without mechanical trouble.

The contest this year differed in many respects from those of the several preceding years. It may have been severer than any contest previously held in this country-this was the verdict of many "veterans" taking part-but it is doubtful whether it really can compare with the New York-Pittsburg Tour of 1903 for severity. Had the weather conditions of the earlier tour been superimposed on the long daily distances of the recent one, all records for severity would certainly have been broken. As it was, the hot weather was no doubt quite severe on the tourists, but motor cars are little affected by high atmospheric temperatures, and aside from the heat the weather was favorable all through.

According to reports there was again considerable grumbling and crimination toward the end of the tour. In our opinion it will never be possible to separate this entirely from a contest of this kind, for the reason that a severe endurance test of automobiles cannot be had without submitting the drivers to a very severe test of physical endurance, and it is a well known fact that many men are ill tempered when in a state bordering on physical exhaustion. Endurance contests, in order to be of any value at all, must be made more severe each year, because cars are constantly being made more reliable and more durable, and in this development a point must eventually be reached where further progress is checked by the limits of human endurance. Indeed, it is quite obvious that even now the skill and endurance of the drivers is an extremely important factor determining the records of the individual cars. For instance, toward the end of the tour washouts about 6 feet wide were encountered which proved the undoing of several competitors. Such an obstruction is dangerous or not according to whether it is seen in time. A driver who is exhausted by the strain of long, continuous driving over rough roads and lack of sleep is naturally much more apt to fail to see it in time than one who is fresh and alert.

A new feature of this year's tour is the technical examination, and, as might have been expected, this really determined the winners. That is, there were still a number of clean scores in both the Glidden and Hower competitors when the cars reached Kansas City, but the technical examination led to the imposition of penalties which eliminated all but one perfect score in each contest, and proved therefore the deciding factor. The honor of victory is naturally prized very highly among so many contestants, but a creditable showing just failing of victory is undoubtedly gaining in value, relatively. With the great multiplication of contests a man is not likely to be much impressed by the fact that a car won a certain contest unless he actually read an account of the contest and knows the conditions under which it was held. And if he does read the reports he must perforce admit that the car which came through with no more serious damage than the breaking of a fender iron made practically a perfect record.

That the Glidden Trophy has been won for the fifth time and the Hower Trophy for the second time by one and the same make of car is unique in the annals of automobile competitions. It would seem to show the value of what might be called specializing in the participation in contests. The manufacturer of these cars never enters races, and his cars are seldom seen in other contests than the Glidden Tour. But for this one great event of the year evidently the most thorough preparations are made, the best drivers secured, etc. This manufacturer entered four cars, more than any other single manufacturer, and, therefore, had originally the best chance of winning at least one prize. But the showing made is, of course, far better than could be explained on the basis of superiority of numbers. It should be pointed out, however, that this year's Glidden Tour was not very strenuously contested, in so far as most of the leading American makes, ranking with the winner in popular estimation, were not represented.

The Glidden Tours are undoubtedly on the decline, as is shown by the annually decreasing number of entries, and at the moment it appears extremely doubtful whether the tour will be repeated again. Of course the more the number of entries shrinks the greater the chances of the individual entrant, and this is one feature which keeps alive competitive events that are disapproved of by the industry on the whole. New York-San Francisco has been suggested as a suitable route for next year's contest, but we do not believe the plan will appeal to the manufacturers.

#### Writing for the Technical Press.

The habit of writing for trade papers often proves valuable in more ways than one, and it seems strange that so small a percentage of the mechanical men in the automobile trade have yet formed it. Of course, this has always been a "high pressure" industry, where liberal salaries are paid to good men, and where these men are kept pretty busy. Nevertheless, there are a great many who are fully capable of writing interestingly and have sufficient time to do so, who have either never given serious thought to the matter as related to themselves or have failed to overcome their mental inertia sufficiently to actually set to work.

In older lines of manufacture there are a far greater number of workers who find it profitable to contribute to trade papers. Besides the money received directly, which often makes the work very profitable when only the time spent is considered, contributions sent regularly to a reputable journal may be regarded as a form of insurance against lack of employment. Owing to changes in organization or plans even the best specialist is liable to be thrown temporarily out of employment. But if he has been sending contributions regarding his special line of work to such a paper as THE Horseless Age he has, without knowing it. been forming a national reputation for himself. His articles have been read by numerous factory heads, by men who employ others to do the work they have neither the time nor the training to do. As a consequence they know him, his methods of thinking and working, and have already estimated his ability, for the man who leads always measures the minds with which he comes in contact. Hence it is much easier for a contributor to the technical press to get employment from those who have read his articles than it is for a stranger.

This is not theory but a proven fact, and the following incident, which occurred a few weeks ago, furnishes a good illustration of this assertion.

A manufacturer of automobile specialties wanted a man for a position which required technical ability and some knowledge of salesmanship. The position was a good one, paying several thousand dollars a year. After a mental canvass of all the men he knew of connected with the trade, the choice narrowed down to four contributors to our columns. One of these was finally engaged.

#### Profits in the Automobile Industry.

The large profits reaped in the past several years by a few firms engaged in the manufacture of low priced automobiles seem to have had the effect of encouraging the organization of new companies on an unprecedented scale, and great efforts are at present being made to interest new capital in the automobile industry. As is usual under such conditions, the few exceptional instances where enormous profits have been made are held up as typical examples, and the promise of similar profits is held out as bait to the investor.

It is undoubtedly true that a few men have made fortunes in the automobile manufacturing business in a short time by correctly prejudging the trend of the public demand and putting through such large lots of cars as to enable them to sell at unusually low prices. But these cases have been exceptional, and not every company that prepares to turn out cars on a large scale can hope to meet the same success. Some of those who have made enormous profits recently had been producing cars for years without conspicuous financial success. Moreover, the general increase in the output of low priced cars is bound to make competition in this line much keener inside of a few years.

In view of the highly colored newspaper reports of profits made in the business, we believe investors should be informed of the real state of affairs. On the average the profits made in the industry the past four or five years have been very moderate. A great many manufacturers have had difficulty in making ends meet, and for every one of the phenomenal successes there have been at least a dozen failures. The manufacturers' committee on the tariff in its brief to the Ways and Means Committee made the significant statement that "it was doubtful whether twenty of the 253 manufacturers of automobiles in the country could show a fair profit." With the standardization of design and the widening of the markets the chances of profitable business in the industry have undoubtedly increased; but, on the other hand, sooner or later, the danger of overproduction must be faced. Then the strongest companies, those with ample financial backing, capable engineering staffs, and efficient manufacturing equipment, will survive, while the weaker ones will be forced to the wall. The boom period cannot last, and those who invest unwisely in automobile companies are likely to lose their investment.

#### Calibration of Carburetors.

Carburetor action is admittedly a very complex phenomenon, and very involved mathematical formulæ are required to represent the variation of gasoline emission from a spray nozzle with varying suctions, However, the law of a perfect carburetor is ideally simple, and very simple tests are needed to show whether a carburetor follows this law fairly closely throughout the range of engine speed. Although the point has often been disputed, we believe that a carburetor that gives a mixture of constant proportion throughout its whole range of action fully meets the requirements in this respect. Most of the best carburetors at present on the market give a fairly constant mixture over a considerable range, but when the suctions attain extreme values the proportion usually changes materially. the mixture being always rich at intense suctions (high speeds) and lean at weak suctions (low speeds). The problem now consists in extending the range of substantially constant mixture proportions, especially in the direction of weaker suctions, so as to enable motors to be operated at extremely slow speeds without popping in the carburetor and without unnecessary waste of fuel.

An experimental study of the subject has been made by Frank H. and Fred O. Ball, who describe their experiments elsewhere in this issue. Messrs. Ball reach the conclusion that a carburetor can be made to give a mixture of constant proportions at practically all suctions, and the most important feature of such a carburetor is a calibrated spring; that is, a spring which will compress definite amounts under all suctions. Nothing further is said as to the conditions, but presumably the outline of the supplementary air valve must be made of special form.

The great importance of accurate automatic regulation of the mixture proportion is well shown by the results of recent economy contests. Of cars of fairly similar design one often produces more than twice the ton miles per gallon of fuel as another, and there can be little doubt that the most important factor producing this difference is lack of automatic carburetor regulation in the least economical car. If the same amount of power were generated in both, and the excess loss in one expended in overcoming bearing friction, etc., the bearings on that car could hardly fail to give incessant trouble from overheating and to wear out rapidly.

#### The Sixth Annual A. A. A. Reliability Tour-IV.

BY CHESTER S. RICKER.

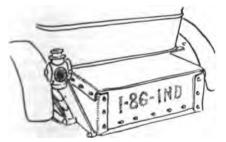

#### Denver to Hugo.

Hugo, Col., July 27.-Much trouble was experienced by the cars today with their carburetors, but this was due to a large extent to the high elevation, the highest point on the entire tour being reached. At Palmer Lake, 47 miles from Denver, the elevation was 7,235 feet, and the rise between the two points was 1,955 feet, or almost 42 feet per mile average grade. It is evident, however, that not only the elevation but the grades encountered had some effect on the operation of the motors.

The greater part of the distance the roads were good. To Colorado Springs, 80.5 miles, they were excellent, except for a few short stretches of sand. All the hills were quite steep and in several cases resembled a roller coaster, so quick was the drop when traveling 35 or 40 miles an hour. After leaving the Springs, however, the roads grew more sandy, until about 110 miles from Denver we again traveled over the narrow grass grown prairie roads. The grass grows so high on these that one cannot see more than 150 feet in advance, and, to make it worse, the roads are very winding.

#### STOP AT COLORADO SPRINGS.

The route to Colorado Springs was along the base of the mountains. Pike's Peak was in sight almost the whole distance. Arriving at the Antlers Hotel all the cars checked in at a control which was provided. Police watched the cars during the stop, in order to permit the tourists to visit points of interest thereabouts. Two hours was considered sufficient by Chairman Hower for the purpose. Our party checked in and hired an automobile to take us through the "Garden of the Gods" and over to Manitou Springs. This trip took about an hour and a half. The remainder was spent in indulging in the first hot lunch which we have had during the tour. A large portion of the

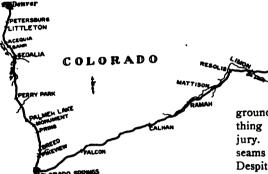

Marmon Suit Case Rack and Cover.

American Simplex, No. 51.

contestants did the same, and I have only mentioned our experiences as an example. ON THE ROAD.

For the first time during the tour the writer did not ride in Webb Jay's Premier No. 1. An opportunity was given to ride in the American Simplex Detroit Trophy contestant, No. 51, driven by Walter A. Wood. This car has the only two cycle motor used by a contestant, and in addition is reputed to have the finest spring suspension of any car in the tour. To verify these

statements the writer was only too glad to accept the offer of a seat.

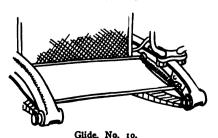

The run to Colorado Springs was uneventful. We arrived at 10:04, two hours and fifty-six minutes for 70 miles' running. The riding was superb. Although the writer has ridden in many fine and high priced cars it was a surprise. Further evidence of a still more strenuous character was in store, however. Two washouts were met along the road. Recent rains had washed a 6 foot ditch straight across the road in the first case. No danger sign was posted, and

Special Covers on Moline Cars

Chalmers, No. 52.

and we plunged into the other side of the washout. As it was only about 4 feet wide we were hung up on our frame. After an hour's work and the combined efforts of the crew and the Studebaker and Maxwell press cars, our car was dragged back to level ground again. The radiator was the only

it is surprising that only one car had an ac-

cident. Teddy Day escaped it by a hair's

breadth. The confetti car dashed into it.

but only one wheel dropped off, and as the

car was light, little difficulty was experi-

enced in getting it back on the road. It re-

mained, however, for the car in which the

writer was a passenger to go in right. We

were traveling about 30 miles an hour when

the ditch, only 100 feet away, seemed to rise

up to meet us. Wood did everything in his

power to stop and get out of the deep ruts

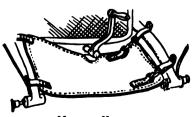

in which we were traveling. So deep were

the ruts that the effort was without avail.

thing on the car which did not escape injury. This rested on the ground, and the seams of the lower tank were badly opened. Despite this we continued the remaining 70 miles, and although we had lost nearly an hour in removing the car from the hole in which it was, we checked in on time. To make a three and one-half hour run in two and one-half hours over roads on which one could hardly see more than 100 yards ahead most of the time took skill on the part of the driver and a good motor to keep it going. The easy riding which I have referred to before was a factor in making this speed possible as far as comfort is concerned—the motor did the rest. The motor is so noiseless that at many times it was impossible to tell from the back seat whether it was running. There is much expression of regret among the other tourists that a perfect score should be spoiled by such an unfortunate accident. If a sign of some character had been posted it would have been different, but such was not the case, and it is very fortunate that no one in the car was killed.

Maxwell, No. 107.

Marmon, No. 4.

How Some of the Cars Were Rigged Up for the Tour.

RUNNING TIME.

Class A-8 hours 40 minutes.

Class B-8 hours 55 minutes.

Class C—9 hours 10 minutes.
Class D—0 hours 55 -9 hours 25 minutes. Class E-9 hours 40 minutes.

Distance, 173.5 miles. A two hour stop under control was allowed at Colorado Springs, the observer noting the time of arrival and departure. PENALTIES.

Two clean scores were spoiled today. One of the cars incurring its first penalty was, as was stated above, the Simplex. No. 51. The other car which lost its clean bill was the White steamer, No. 14, driven by H. N. Searles.

In detail the scores are as follows:

American Simplex, No. 51, 1.2 points for time working on the radiator and tightening the steering gear, which was severely wrenched when the car was ditched. To this was added 0.2 point more for material which was used to try and stop the leak in the radiator. Altogether this made 1.4 points against the Simplex. This leaves the Premier entry, No. 53, the leader in the Detroit Trophy class, the scores of the competitors in this contest being as follows: No. 53, Premier, 0.8 point; No. 51, American Simplex, 1.4 points, and No. 52, Chalmers, 6 points. Thus no competitor in this class has a perfect score. The White steamer received 16 points for tardiness and 2.2 points for repairing a lubricator pipe, this making a total of 18.2 points against it.

Through some mistake in calculation of the penalties on July 21 a penalty of 16 points was imposed on the Jewel, No. 7, but this has been reduced to 8.8 points. No. 10, Glide, which had spring trouble last Saturday, today replaced the spring which was reported as replaced at that They then only made a temporary time. repair by winding it with wire, so as to reach Denver at least. Today they replaced it completely. The penalty, however, has not been reported.

Neither the Hupmobile, No. 106, nor the Brush, No. 104, arrived tonight. The Hupmobile is reported to have broken a connecting rod, while the Brush is said to have turned turtle in one of the ditches. No confirmation has been received, but the car has not shown up either.

HOW THE CARS HAVE CLIMBED.

Council Bluffs, elevation 981 feet.

Rise 1,145 feet in 200.2 miles to Kearney, 2,126 feet.

Rise 1,324 feet in 206.2 miles to Julesburg, 3,450 feet.

Rise 1,830 feet in 204.8 miles to Denver, 5,280 feet, one mile high.

Rise 1,955 feet in 47 miles to Palmer Lake, 7.235 feet.

Descent 1,245 feet in 23 miles to Colorado Springs, 5,990 feet.

Descent 990 feet in 102 miles to Hugo, 5,000 feet.

#### Hugo to Oakley.

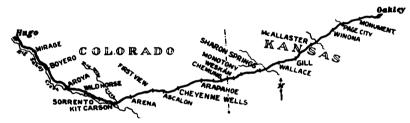

OAKLEY, Kan., July 28.-The latter part of yesterday's run was bad, but today's run was the limit! So rough were the roads that it was impossible for the cars to average better than 12 or 15 miles per hour

for the first 40 miles. That is to sav. the cars were about an hour late after running only three hours. Worried by this lateness. and not certain as to the condition of the roads which were to come, most of the cars "burned up the roads," irrespective of the condition, after that. Of course, the roads improved somewhat later in the day, but were no better than those encountered during the last three days.

Not only did these roads tax the endurance of the drivers, but they eliminated two cars and broke the perfect score of another. The Mason, No. 112, which had been doing so well up to now, arrived The press cars also had their very late. fill of trouble today. The Studebaker press car, No. 81, driven by Harry McIntosh, broke both front axle spindles, it is reported. The other press car, No. 80, also had an accident which smashed the radiator. To the Maxwell press car, No. 82, is due the credit of towing in the big Thomas which was disabled. Pete Esty, one of the reporters on the tour, remarked tonight that even if the press cars did get through the press men had to work their passage. He was on the Maxwell, and knew. Howthe water nump connection was broken at the same time, and before Buse knew it the motor ran hot and "froze" fast. The explanation given of the accident is that the brakes did not hold well enough to stop the car before it came to the ditch. Withdrawal, of course, was the only possible procedure under the circumstances.

Maxwell, No. 6, driven by Gager, was unfortunate in losing a clean score today, and was the only car to do so. The penalty was incurred by the replacement of a spring which had broken the day before. The points were 4.5 for material and 4 for labor, making a total of 8.5 points

The other Maxwell, No. 107, had the same trouble; that is, a front spring had to be replaced. Goldthwaite, the driver. thought it best to replace the spring, although it was not entirely necessary to do it; 4.5 points were imposed for material and 3.2 points for labor, making 7.7 points total for today. Many of the tourists have commented on the consideration which Goldthwaite has given to the other users of the road. When he is passing another contesting car he always drives as fast as possible so as not to throw dust in

ever, many of the competing cars are much indebted to the press cars for helping them out of the numerous mud holes and ditches in the first part of the day's route.

#### THE ROAD IN BRIEF.

The route from Hugo to Kit Carson lay along the edge of the Big Sandy River. On account of the heavy rains which had fallen here lately the surface of the road was cut up by narrow, deep cross gutters from the hillsides. These were not more than a yard apart for miles on end. But this was not the worst. Several mud holes and washouts further helped to delay the contestants. After leaving Kit Carson the roads were much better, and many of the cars arrived here anywhere from a half hour to an hour ahead of their schedule.

#### TROUBLES IN DETAIL.

The first cars to come to grief were the Studebaker press cars, Nos. 80 and 81. The first, No. 81, broke both front axle spindles, and is practically out of the run. The other, No. 80, broke its radiator, and has not arrived here yet. The train service here is not what it is in the East, and it was not until late that the stranded press men reached here.

Thomas, No. 11, driven by Gus G. Buse, has met its finish. Near Monument, about 11 miles from Oakley, the Thomas struck an unseen ditch while traveling at a high rate of speed, and the sub-frame was broken. This was not the only trouble, however, for

the faces of the occupants of the other car. On the other hand, when one desires to pass him he always turns aside and gives one the whole road if possible.

Glide, No. 10, driven by A. Y. Bartholomew, received its penalty tonight for a spring which was replaced yesterday, 12.4 points being charged for the spring and 16.4 for the time required to replace it. Further trouble occurred today which will probably cause the withdrawal of this car also. One hundred and thirty miles out of Hugo the front spring perches revolved around the axle, and at the same time the steering arm broke, causing the car to dash from the road. On the way in here the axle turned around five or six times and great difficulty was experienced in reaching here at all. No penalty was announced, nor is it definite what will be done with the car.

Shortly after 10 o'clock the Mason, No. 112, arrived. The tie rod between the wheels is reported to have broken and to have caused the trouble and delay. The Chalmers press car, No. 83, turned out a crank pin bearing.

#### TIRE TROUBLES.

Trouble with the tires has been quite frequent today, although not in any way so bad as might have been expected in view of the condition of the roads. The only cars having trouble were Nos. 1, 2, 4, 6. 9, 14. 102 and 52. Until today Chalmers,

No. 52, had not had any tire delays. Jean Bemb, the driver, had been trying to go the whole tour with Detroit air in all his tubes, and all but succeeded.

#### WATER IN THE GASOLINE.

A humorous but disagreeable incident occurred this afternoon on checking in at the night stop. Premier, No. 1, and Chalmers, No. 52, were taking on gasoline side by side. The Premier carries a 5 gallon gasoline can filled with water for emergencies. As the can was exactly similar to the ones in which the gasoline was brought to the cars, one of the garage employees took it by mistake and poured about a gallon of water into our tank. The mechanic, however, discovered it before more was poured into it. Shortly afterward the same boy unthinkingly poured the remainder of about 4 gallons into the Chalmers tank. We were able to make the control, but the Chalmers was not so fortunate. The chairman, however, will permit the driver of that car to drain and refill his tank without any pen-

#### RAPID TRUCK UP PIKE'S PEAK.

Sunday the Rapid truck, No. 75, which has been acompanying the tour, left Denver at 4:15 a. m. It reached Colorado Springs at 11:30 p. m. It left the next morning at 6:15, and nearly reached the top of Pike's Peak when it was enveloped in a cloud and was unable to proceed further, owing to the dangerous nature of the road. The night was spent on the peak. Grogan, the driver, was lost from the party, and not "ntil morning did he find his way back. The car reached the summit early the next noming, however, and after finding that it would cost \$100 to take the car down by rail it was brought down on its own wheels. The crew consisted of the driver, Grogan, the mechanic and a photographer. At 3:30 5 m. this morning (July 28) they left Colorido Springs to catch up with the tour.

#### Oakley to Salina.

SALINA, Kan., July 29.—This day has been the most trying to the drivers in the tour so far. The heat was intolerable, and here were several cases of near-prostration. Mr. Glidden took the temperature en route, and stated that at one time it was

122 degrees on the road. In the shade it was over 100 degrees. To drive 199.7 miles in this furnace was the fortune of everyone on the tour, except the chairman and a few of the press men, who could not find seats in the cars.

Except for the heat the run would have been very pleasant. The roads were very good, except for some hills in the afternoon, which were rough and stony. None of the cars had any difficulty in making the schedule, and many were an hour or more ahead.

One certainly seemed to be getting back into civilization again when towns were found every 10 or 12 miles. The people also were enthusiastic over the tour, and in every town the cry is to "let her out," so they can see the great race. They seem disappointed in many cases when they learn that the Glidden Tour is not a race. Many automobiles are now met along the road, whereas only the day before yesterday it was a rare sight to see a house.

The roads, instead of being bare of vegetation and bounded only by the horizon, are lined with fields of corn, oats and

No. 53, the Premier Detroit entry, had to stop and wire the rod pan in place, and received a penalty of 1.5 points.

The Jewel, No. 7, also received a penalty, but for a repair which was made on the 29th. The fan belt was tightened, and for the time consumed 1.7 points were assessed, to which 0.6 point was added for material.

No. 11, the Thomas, was withdrawn. The reason given for the withdrawal was stated in yesterday's report.

RUNNING TIME.
Class A—10 hours.
Class B—10 hours 20 minutes.
Class C—10 hours 40 minutes.
Class D—11 hours.
Class E—11 hours 20 minutes.
Distance, 199.7 miles.

#### Salina to Kansas City.

Kansas City, Mo., July 30.—Weary and dust covered the tourists finally arrived at the end of their 2,657.3 mile journey. Kansas City welcomed us with open arms. As Dai Lewis predicted, the day's journey was the hardest that we have had during the tour. In addition it was the only day we have had rain during the tour. The rain

wheat. Indeed, this is one of the chief grain raising States of the Union.

#### PENALTIES.

There were few penalties tonight. The Glide is the only car not in yet. The penalties for last night, which were not announced at that time, were given out tonight. No. 10, the Glide, was one of the penalized cars, the Mason, No. 112, the other.

The following are the penalties: No. 10—material, 0.2 point; outside tools, I point; labor, 56 points, and lateness, 296 points. This makes a total of 353.2 points for last night. All the trouble was with the springs and the steering gear, as was mentioned in yesterday's report.

The Mason, No. 112, which had a heated piston pin, caused by running out of water, was penalized 6.3 points for material and 25.7 points for labor required to put it in condition again. Lateness added 215 more points, making a total for the day of 247.

Among the other cars receiving penalties were the White, No. 14, which received 0.4 point, 0.3 of which was for time taken to wire a fender in place and 0.1 for material.

No. 111, Jewel, had to repair the gasoline pipe line and received 1.1 points; for cleaning air pressure line it was penalized 1.5 points, making a total of 2.6 points.

was welcome, inasmuch as it cooled the air and laid the dust, which latter was very discomforting yesterday. On the other hand, it made the roads very slippery, as those with a gumbo bottom always are under the circumstances. At Topeka it was reported that over an inch of rain had fallen during the night, and the condition of the roads quickly made this evident.

Two perfect scores also fell by the way today, thus leaving only eight perfect road scores. The cars losing out were the Lexington, No. 114, and the Chalmers, No. 105. Cars which received further penalization were the Maxwell, No. 107, the White steamer, No. 14, and the Premier, No. 53. Among the cars which were seen in trouble today was the pilot car, an E-M-F, which was passed about 16 miles out. The car had been abandoned, and it appeared as if it had had rear axle trouble. At 188 miles out the confetti car also was passed. The reason given for it not being "on the job" was that with the terrible condition of the roads it was impossible to keep up to the schedule. The Premier pacemaker, No. 99, picked up the pilot, Dai H. Lewis, and brought him into Kansas City. The Studebaker press car, No. 79, was passed on the road, and was evidently in difficulty, as the American Simplex, No. 51, was endeavoring to tow it. The little

Maxwell press car, No. 82, had its magneto fail, and had to go back through the mud about 2 miles to get batteries in order to get through.

So slippery were the roads immediately after starting that it required the use of tire chains on both front and rear wheels to keep the cars any where on the road. As it was the cars would slide from side to side, often having very narrow escapes from serious mishaps. This continued as far as Chapman. For about 15 miles beyond, however, the roads were dry and dusty, and then again they became muddy, and remained so all the way here. The first part of the way was quite level, but the country became more hilly as we approached Topeka, and beyond was very hilly and muddy. Instead of gumbo we now had a slippery clay, which was probably worse. Except for the first hour the day was without rain. The distance was the longest which the contestants had had yet, and coming at the end of such a long and arduous tour it was not without its

Class A—10 hours 39 minutes.
Class B—10 hours 59 minutes.
Class C—11 hours 19 minutes.
Class D—11 hours 39 minutes.
Class E—11 hours 59 minutes.
Distance to be covered, 212.8 miles.

ON THE ROAD.

THE HORSELESS AGE representative was a rear seat passenger in the Pierce Arrow, No. 8, driven by the veteran tourist "Teddy" Day. The big Pierce checked out at 7:07 and finished the run at 5.33, over half an hour ahead of time. All four of the perfect score Pierces checked in first today. As we were in the lead of the procession after a few hours, little was seen of the remainder of the contesting cars. Little can be said about the Pierce which is not already known. Being a large car it rode as all such should ride, and an average speed of 25 miles an hour was maintained throughout the day, irrespective of the road conditions. This, it should be considered, was over roads which were anything but passable, and yet the trip was without the least fatigue to the passengers.

#### HOW THE DRIVERS DRIVE.

It has been a most interesting study to note the way the various cars are driven. Take the little Brushes. Their drivers open the throttle wide and let them go at the same speed whether on straight away or on turns. They are so short and their speed is such that this is possible. Another car which has come in for much comment is the Mason, No. 112, driven by Roy Snyder. Whenever the writer has had an opportuni-

ty to observe this car on the road he noticed that it was driven very much in the same manner as the Brush cars. For a little two cylinder motor with a long stroke it surmounts hills on high gear in a surprising way, and the car plugs away on high gear most of the time.

With some of the larger cars the drivers negotiate turns at high speed, and also run fast on the straight stretches. On hills the majority of the drivers try to hold their high gears as long as possible, and probably strain their motors far more than they would if o lower gear was used sooner. This, however, was not the manner of driving employed by "Teddy" Day. His methods, which have been so successful in former years, may be of interest to readers. Seldom does he take a corner faster than to miles an hour, which is probably the reason why he experienced only one puncture during the whole tour and carries Detroit air in three of his tubes. It is on the straight stretches and on the hills that he makes time. On the hills, especially, he gains minutes over most of his competitors by using his lower gears before the motor begins to pull hard, and thus keeps up his average rate of speed.

#### HOW SOME OF THE CARS LOOKED.

The cars were undoubtedly severely tried by the road conditions today after such pounding as they have had. Many steering gears are very loose, and this will appear in the report of the technical committee in a few days. Much to the surprise of many axles have given very little trouble. The Glide, No. 10, has had some serious difficulties with its steering arms as well as the spring seats working loose and the axle turning over. The Jewel, No. 7. came in tonight with the front axle slipped fully 5 or 6 inches farther forward on the left hand side than is normally the case. The other Jewel, No. 111, broke a front spring and came in with the axle lashed to the frame. Another car having trouble with running gear was the Midland, No. 12, which has the right rear wheel spokes so loose that the wheel is almost on the verge of collapse. On the Premier cars all the fan belts are off. In each case the hook connecting the ends of the belt let go and the belts came off, and, remarkable to say, the motors kept quite cool if the sides of the hoods were left open. This the drivers always did. Two of these cars, by the way, broke their rear springs just where they are attached to the frame. The last two days two have been riding on the rear axle bumper. Cars Nos. 12 and 8 have no starting cranks. The crew of Midland, No. 12, is in the habit of jacking up the rear wheel and starting the motor in that manner. The Pierce runabout, No. 109, driven by Scofield, dropped its trunk rack and tool box on the road, and is now carrying them strapped beside the rumble seat.

#### PENALTIES.

Cars Nos. 1 and 2, both Premiers, 8 and 9, Pierces, and Marmon, No. 5, still have

THE ARRIVAL IN KANSAS CITY.

ills in the Glidden Trophy contest. Hower contest only the Moline, No. d the two Pierces, Nos. 108 and 109, ean scores.

White, No. 14, had added to its score I point for material and 6 for, making a total of 7. Moline, 12, likewise had added 29.5 more to its demerit score, of which 16 r tardiness, 13.3 for labor and 0.2 terial.

to5, the Chalmers roadster, which is by Machesky, injured the edge of its rims today and replaced the wheel on which the injured rim was. w wheel was taken from the Chalress car, No. 83, and since it was rom another car the penalty is dis-

hwaite's Maxwell, No. 107, had trouble with its spring and had to a blacksmith's to have it repaired. stailed a penalty of 23.5 points, ditailed a penalty of 23.5 points, ditailed a penalty of 23.5 points, ditailed a penalty of 23.5 points for tardiness, nt for material and 2 points for

111, Jewel, added some more points penalties. It was charged with 0.4 or material and 4.6 points for labor, a total of 5 points.

Lexington, No. 114, was penalized 0.2 or tightening the driving member rear axle, which, of course, was sufto spoil a clean score. This means road score. The scores may stand by differently when the technical tee gets through with its examina-

ateness the American Simplex, No. 3 given 4 points penalty. No. 53, mier in the same contest, had to rehe rear spring which was broken sday. The penalty thus incurred has been announced.

o'clock tomorrow morning the techmmittee will take charge of the cars,

HE TECHNICAL EXAMINATION.

ning at 8 o'clock on Saturday morncommittee were kept busy examincars for defects which would re-

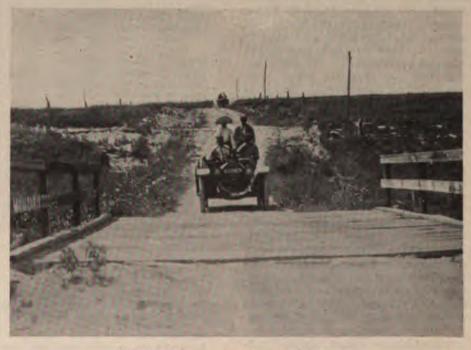

PIERCE, No. 8, ONE OF THE FOUR PIERCES WITH PERFECT ROAD SCORES.

quire replacements and thus penalize them until 2 o'clock Sunday morning. This, as may be imagined, was not very satisfactory to the contestants who had to be with the cars which were being examined at that late hour. Most of the drivers and observers had risen about 4 on the morning of the run to Kansas City, and very few were able to get much rest that night, so hot was the weather. This was followed by an all day wait until their particular car was examined, and so they were naturally extremely fatigued. Sunday morning the examination continued, and it was finally completed at about 3 o'clock in the afternoon. Several of the tourists expressed

dissatisfaction because they could not attend the automobile races which were held on Saturday.

In making the examination the technical committee took into consideration the condition of the various parts of the mechanism. Each part was gone over separately, either by Joseph Tracy or Henry Souther. Usually one took care of one kind of parts and the other of another kind. After each car had been subjected to this technical examination it was taken out on the road and given a short test run to determine the condition of the running gear and of the motor. The brakes were also tested at this time. Although there was no penalty for

MARMON, No. 5, WITH PERFECT ROAD SCORE.

#### THE HORSELESS AGE.

brake adjustment, the committee tried both foot and hand brakes on each machine. In most cases adjustments had to be made, and it was intended to penalize such cars as could not make such adjustments. All the cars, however, were able to slide their wheels before they were finally passed upon. The braking equipment of the Premier and the Marmon cars proved exceptionally good, for it was claimed that they had not been adjusted on the tour, and it was observed in each case that either brake was sufficient to slide the wheels. The final examination on Sunday consisted of going over the frames, and after a thorough examination only one frame was found the worse for the hard pounding that had been given them. This was on the Jewel, No. 7, which had a crack along the edge of the left front side member, extending several inches in either direction from the lamp bracket. The penalty imposed was for a new side member and not for a whole new frame

#### THE ROAD EXAMINATION.

As the road examination was given with the hoods off and with the footboards out in most cases the noises which are usually muffled were quite evident to the examiners. A short hill was included in the test, and most of the cars were required to use their second speed in climbing this. The noise arising from the gears in some cars was quite disagreeable. On the other hand, there were cars which were as remarkable for their quietness. Marmon, No. 4, and Maxwell, No. 6, were chief among these. The drivers of the Pierces, on the other hand, acknowledged that the noise of their gears was objectionable to many people, but that it was the policy of the company to make them give out a certain amount of noise, a policy also followed by the Panhard Company. The motor on Frank Wing's Marmon ran perfectly, and was inaudible, except for the whispering noise of the carburetor. The motor of the Maxwell, No. 6, also ran very smoothly. These are both motors with valves on opposite sides. The Pierce motors, which also have "tee" motors, were next in order. Strange to say, the motors with valves all on one side, which, making the exception of the Mason, was the only other type represented at the finish, were always more noisy. Aside from motors built by the car manufacturers themselves there were four Rutenber and one Beaver motors represented. Most of the transmissions were those made by the Warner Gear Company, and had roller bearings. On the Chalmers, No. 52, and on one of the Moline cars the roller bearings worked loose, the retaining rings in each case loosening up and causing the trouble. On two or three axles the housing that supports the pinion bearing of the bevel gears worked loose and had to be tightened. On some axles this only necessitated the screwing of the housing back into place, but on others the cap screws which had worked loose had to be tightened or replaced.

Motor and transmission bolts had to be tightened on several cars. They were not off, as in each case castellated nuts were provided. The noticeable thing, however, was that the left hand ones on the transmission were loose, showing that perhaps the torque reaction was the cause of the loosening. On the motors it was always the right front and left rear bolts that were loose, which was evidently due to the effect of torque couples.

Springs in several cases were broken, and in some instance had a decided set. Some of the cars which had broken springs were Premiers, Nos. 1 and 53; Jewel, No. 111; Marmons, Nos. 4 and 5; White, No. 14; Glide, No. 10, and Maxwells, Nos. 107 and 6. The two Premiers broke the upper half of the three-quarter elliptic springs at the frame support. The Jewel broke a front spring and also the cross member of the platform spring in the rear. One front spring on the White was broken at the spring seat, and the other had a bad set in it. The Marmons both had a front spring leaf broken, and in each case it was on the driver's side. Their springs, by the way, were the lightest on the tour. The Maxwells and the Glide had broken springs, but the real cause of their trouble was that the spring seats were broken off the axle. This is a good point for the integral spring seats, which gave no trouble at all during the tour.

Probably the most chronic trouble on the whole tour was the breakage or loosening up of spring clips. There was scarcely a car which was not penalized for doing some work repairing trouble of this kind. So frequent was the trouble that the committee made a fixed penalty for this, namely, 30 cents charge for a new one and seven minutes penalty for replacing it; thus giving I point penalty in each case. For tightening them up two minutes were allowed for each clip. Those who desired to do the work could have their time taken, and in the case of the Mason two clips were tightened in one minute, whereas four minutes would have been charged if the work had not actually been done in less time. Several faint hearts did not dare do the work for fear that they might exceed the time set by the committee, and so be penalized more. Those who did work had the satisfaction of gaining less penalty.

#### Some of the Replacements.

Some surprisingly quick repairs were made on the cars where the work was done. Probably the quickest was on the Midland, No. 12, where the committee allowed thirty minutes' time for the replacement of a rear wheel. The actual time required for the replacement was exactly four and a half minutes. This is an excellent illustration of the ease with which a wheel can be removed from a Timken

Another of these quick repairs was on the Pierce, No. 8, which had to replace a

starting crank hand grip. Three minutes only were required. On the other hand, probably the most unique and unexpected repair to be made was on the Mason. This was the only car on the tour with a centre chain drive. The chain, when examined, was found to be minus fifty-nine cotter very well. Only the Lexington and the

pins. The surprising point is that in many cases there was absolutely nothing to hold the links in place, as both pins would be gone on the same link.

Despite the bad roads and broken springs the shock absorbers stood the punishment

Jewel, No. 111, were noticed with broken absorbers. It was the writer's experience the cars with shock absorbers could more easily keep up to schedule, as they did not fatigue the driver and "pound themselves to pieces" to the same extent as the others did. The cars employing wrapped springs and straps were notably bad riding. However, three of the cars having shock absorbers broke their springs. All the other springs which broke were wrapped and strapped. The Jewel, No. 111, and both the Marmons, Nos. 4 and 5, had broken springs, although they equipped with shock absorbers.

Probably no previous tour has been so severe on the wheels. The constant chucking against the deep ruts in which the prairies abound early started the spokes, and before the run was completed there were several cars in which observers were hesitant about riding. The lateral thrusts had worked the spokes so loose that by gripping the tires one could rock the periphery of the wheel fully 2 inches out of its normal position. Three cars had this trouble, and one of them had it in both wheels. Tightening the bolts did very little toward removing the trouble. One of the drivers attributed this to the very dry weather which we had, but wheels should be made of wood which is fully seasoned and will not give trouble, despite weather conditions.

With the cars well geared down, as was the general practice, the motor vibration at high engine speeds, as well as the road vibrations, seemed to play havoc with all but the most substantially supported lamp brackets. Within the first few days out of Detroit the cross support rods between the lamps began to break. Throughout the tour this trouble was prevalent. Not only did these rods break, but the brackets went soon afterward. One only had to watch the large headlights on the rough roads for a few moments to appreciate how hard the heavy lamps can vibrate. The broken frame on the Jewel, No. 7, can be attributed to this very cause in a large measure.

#### CONTROL OF THE CARS.

The absence of accelerator pedals on the most prominent cars was noticeable. Neither the Pierces nor the Premiers had them. The manufacturers of both cars state that the accelerator pedal in the hands of a novice is only an instrument with which to abuse the motor and so they do not supply cars with it. All cars had both spark and throttle control by hand levers. Only the Maxwells used the progressive type of sliding gear, the remainder having a three or four speed selective. Except for the Thomas, Mason and Brushes, all had shaft drive, and the tour therefore was practically a complete victory for the shaft drive.

One arrangement which would have been much appreciated by the tourists is means for changing the setting of the carburetor (Continued on page 131.)

## NEW VEHICLES

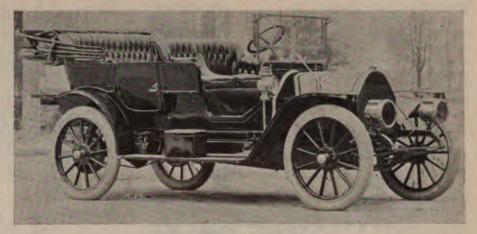

The New Reo Four Cylinder Car.

The Reo Motor Car Company, of Lansing, Mich., have this year for the first time added a four cylinder car to their line. It is a five passenger touring car, rated at 30-35 horse power and selling at

The motor has water cooled cylinders cast in pairs, of 4 inch bore by 4½ inch stroke. The cylinder castings are made of close grained cylinder iron. The crank case is of the barrel type with bolted on circular end plates. Two hand hole covers are provided at one side of the crank case, which when removed permit of readily adjusting the connecting rod bearings. The main bearings of the crank shaft are adjustable from outside the crank case, and easy adjustment of the crank and connecting rod bearings is one of the special features claimed for the new motor.

The crank shaft is of manganese steel having a tensile strength of 110,000 pounds per square inch. All crank bearings are of 11/2 inch diameter, the pin bearings being 21/4 inches long, and the combined length of the main crank bearings 101/2 inches. The crank shaft is offset from the centre line of the cylinders, as is also the cam shaft from the centre line of the valve plungers. The cam shaft is of large diameter, running in three bronze bearings, and is easily removed. The cam gears are provided with helical teeth in order to insure noiseless operation, and operate in an oil bath, which is constantly replenished by the engine lubricating system.

REO 1910 FOUR CYLINDER CAR.

The oiling system is of the pump circulated splash type. A single, large plunger pump is driven from the cam shaft through an eccentric. It delivers oil from the oil reservoir to the three main bearings of the motor, and also to the face of the cam gears. This oil then collects in partition reservoirs in the bottom of the crank case, and is maintained at a constant level. The connecting rods dipping into this oil cause a fine spray which lubricates the cylinders and pistons, the amount reaching the cylinders being governed by splash plates.

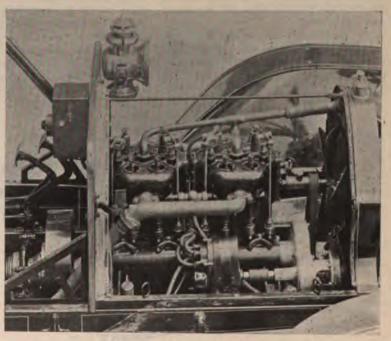

The chief feature of this oiling system is its simplicity. There are no outside pipes or connections, no pump stuffing boxes or driving gears, and no adjustment is required after the motor leaves the factory. The oil circulating pump is claimed to be self-cleaning, for instead of drawing all the particles of lint and dirt into the protecting screen, by steady suction, as would a gear pump, for instance, the screen is kept clean by the pump discharging at least one-half of its

capacity against the screen at each stroke. Instead of carrying a large oil reservoir containing 2 or 3 gallons, a 3 quart reservoir is provided, and thus the trouble arising from a large amount of lubricating oil becoming dirty and full of carbon deposits is eliminated. The system requires the addition of oil every 250 or 300 miles, and this is claimed to be far preferable to carrying a large quantity of oil and renewing it less frequently.

Particular attention has been paid in the design to making the motor oil-tight. The outside main bearings, as well as the bearings of the magneto and pump shafts, have return oil leads. The valve plunger guides have recesses at the top for collecting oil and returning it to the crank case, and are also provided with carefully fitted protecting caps to keep the dirt out and the oil in. There is only a single grease cup on the motor, and that lubricates the fan bearing. The valve lifters are adjustable, and have hard fibre inserts to deaden the noise. The valves are of large diameter, bevel seat-

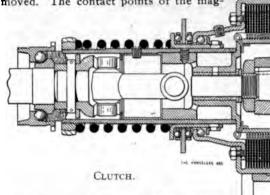

MOTOR ASSEMBLED ON FRAME.

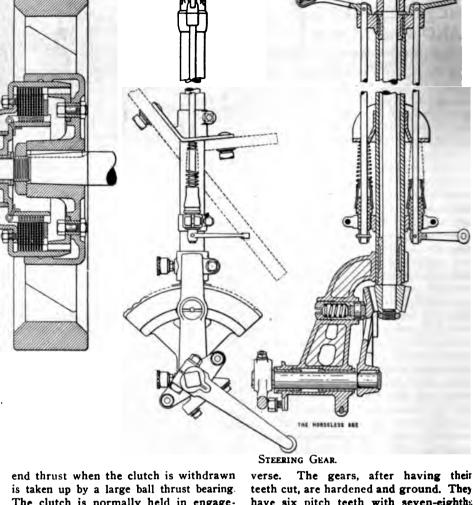

ed, and of the combination nickel steel head and carbon steel stem type.

An automatic float feed carburetor is used which is claimed to admit of a wide range of speed. Ignition is by magneto, with a battery auxiliary for starting. The magneto is attached to its bracket by a single strap and may be quickly removed. The contact points of the mag-

neto are very accessible, and the wiring is short and fully protected. The magneto is connected to its driving shaft by a universal joint packed in grease, and its driving gear runs in oil inside the cam gear casing. The gasoline tank is located under the front seat. It is securely riveted and supported by bands passing around it, instead of by lugs riveted to the bottom. The tank has a capacity of 15 gallons. The cooling water is circulated by means of a centrifugal pump driven from the magneto shaft and accessibly located. The radiator is of the vertical flat tube type and of the same construcstruction as used in former Reo models. It is claimed that it can be easily repaired without spoiling the finish of the outside casing. Back of the radiator is mounted a fan driven by a seven-eighths of an inch flat belt, with a convenient and positive adjustment. The fan runs on ball bearings. The flywheel spokes are also of fan shape and assist in the circulation of air through the radiator and the space under the hood.

The clutch is of the multiple disc type, consisting of alternate discs of hardened steel and phosphor bronze. The steel discs are ground after hardening. The

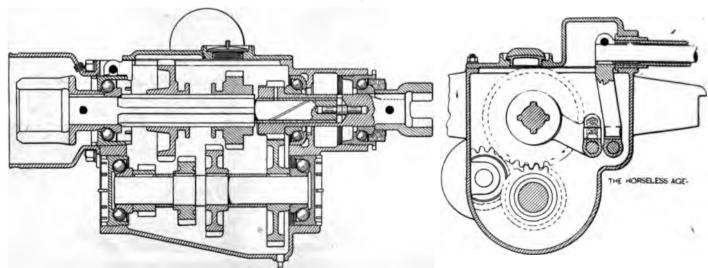

end thrust when the clutch is withdrawn is taken up by a large ball thrust bearing. The clutch is normally held in engagement by a single spring whose tension can be readily adjusted. It is claimed to have positive release, the plates being positively dragged apart by the opening of the clutch.

The clutch is connected to the change speed gear through a double universal joint which is completely encased and packed in grease. This joint is of the full universal type and not the ordinary square shaft with loose sleeve. The change gear is of the selective type and gives three forward speeds besides a re-

verse. The gears, after having their teeth cut, are hardened and ground. They have six pitch teeth with seven-eighths of an inch face. All shafts are hardened and ground, and the sliding pinions are carried on a shaft having four feather keys formed integral with it. The gear case is made in a single casting with removable bearings and a large detachable cover. Except for the shafts of the reverse pinion and pocket gear, all shafts run in ball bearings. All shifting rods and connections are enclosed, and special attention has been given to secure an oil-tight casing.

The rear axle is of the shaft driven

Two Sectional Views of Change Gear.

REAR AXLE WITH BRAKES.

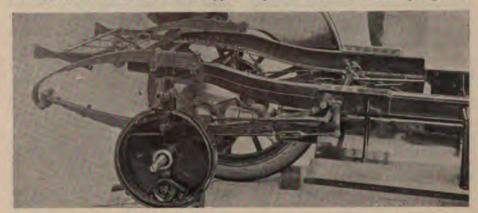

oating type; the bevel driving have five pitch teeth and are after hardening. The standard atio is 31/2 to 1, the pinion and aving sixteen and fifty-six teeth reely. The gear shafts are mounted ustable ball bearings, while the ends of the axles are equipped with bearings, the rollers running in teel sleeves inserted in the axle The compensating gear is of the inion type. The driving gears can usted to the proper mesh by rethe cover of the axle housing and ing the adjusting rings. The torthe bearings are adjusted from the

ngle universal joint is used in the seed drive and is enclosed in a spherical casing forming the forward end torsion tube. The spherical porf this casing is enclosed in a split ring sliding in a pressed steel bolted to the gear case. In this universal connection between the ase and the torison tube is secured. niversal joint is always packed in int, which is fed to it from the gear The torsion tube is a steel tube entitled the driving shaft concentrically.

The latter is of 3½ per cent. nickel steel, heat treated, and runs in adjustable ball bearings.

The car is equipped with two sets of brakes, of the external and internal type one piece drop forging, made of manganese steel and heat treated. The spring seats are forged integral with the axle. The steering spindles are set to make the car self steering, the steering wheels always tending to keep in the straight ahead position. All the bearings of the steering connections have bronze bushings and hardened pins, and grease cups are provided for all wearing surfaces. All steering connections are carried above the axle.

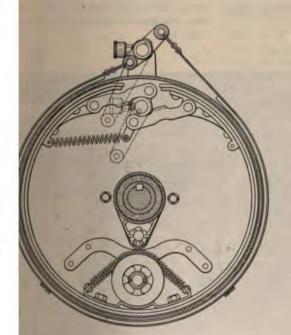

The frame is of pressed steel, hot riveted and carefully braced. The motor and change gear are supported on a dropped sub-frame, which is carried at a slight angle to the main frame, so as to secure a straight line drive. The frame is carried on semi-elliptic springs in front and three-quarter elliptics in the rear, and is "sprung" over

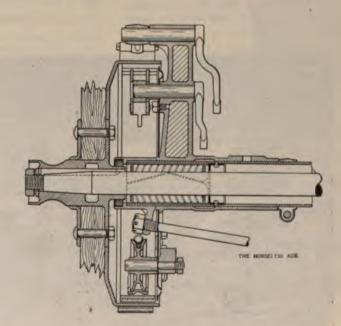

REAR PORTION OF FRAME.

respectively, both acting on the same set of drums, which are 14 inches in diameter and secured to the rear wheel hubs. It is claimed that no strain comes on the driving shaft, axles, torsion tubes or gears as a result of the application of the brakes. The front axle is an I section,

the rear axle to give a large spring clearance and allow the car to carry low. The wheels are of the artillery type; they have twelve spokes each and are 34 inches in diameter. Three and one-half inch Michelin quick detachable tires are fitted. The wheel base is 108 inches and the tread is stand-

HUB BRAKE.

ard, it being claimed that the car will run in ordinary wagon tracks without chafing the tires.

Sheet steel dust plates are fitted between the sub-frame and the side members of the main frame, and a single piece pressed steel under hood is fastened to the subframe by eight locknuts. The car has a clearance of 12 inches under the front axle. which is the lowest part, and of 121/2 inches under the flywheel when loaded. The steering gear comprises a bevel pinion and sector, and is claimed to entirely eliminate back lash. There is only one adjustment, and that is easily accessible. The steering wheel is 16 inches in diameter, and comprises a hard rubber rim on an aluminum spider. The rim has molded finger grips, and is claimed not to wear off or get sticky. The starting crank has four points of engagement on the motor shaft to make starting easy, and is locked in a vertical position by a spring check when not in use.

A departure has been made from conventional practice in the arrangement of the control members. The controlling levers and steering post are located on the left hand side. The change gear is operated selectively by means of a swinging lever, which is claimed to lock absolutely when in the neutral position. The emergency brake lever is located outside the gear lever and operates the internal brakes on the rear wheel hubs, at the same time disengaging the clutch. There are two foot levers, the right one controlling the external brakes on the rear wheel hubs, and the left one controlling the clutch. An additional small foot lever serves to operate the muffler cut-out. Spark and throttle levers are located on the steering post.

The body is designed to comfortably carry five passengers. The tonneau seat is 40 inches wide inside the upholstering at the cushion line, and the front seat 40 inches. The front seat is semi-divided, giving both the driver and passenger ample

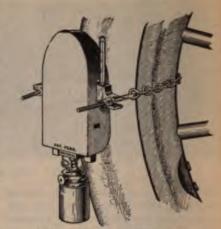

elbow room. The body is finished in blue black, striped with light blue, and is fitted/ with mahogany trimmings and door panels.

The Keystone Light Six.

The Munch-Allen Motor Car Company, of DuBois, Pa., have brought out a small six cylinder car, deliveries on which are to begin next fall. The cylinder bore is 3% inches and the stroke 4% inches, which would make the horse power, according to A. L. A. M. rating, 30. The cylinders are cast in pairs with the valves in the head and operated by push rods on the inlet side. The motor is oiled by a positive gear driven pump inside the crank case, with leads to all crank shafts, connecting rod and cylinder bearings. A film tube radiator is employed and a ball bearing fan is mounted back of it. The cooling water is circulated by means of a gear driven pump. Ignition is by jump spark, and an option is given on two makes of American magnetos. A standard carburetor is supplied.

The motor and change gear are built into a single unit, which is supported at three points. The crank chamber of the motor has sidewardly extending arms at its forward end which rest on the side frames, while the rear end of the gear case is supported by a dropped cross member of the frame. A multiple disc clutch comprising twenty discs connects the motor with the sliding pinion change gear which affords three forward changes of speed and one reverse speed on the selective principle. The drive to the rear axle is by an enclosed propeller shaft, 13% inches in diameter, which is provided with a single universal joint at its forward end. The steering gear is of the worm and worm wheel type, mounted on ball bearings. The hand wheel is 17 inches in diameter and is surmounted by the finger levers for the throttle and spark, which move over a stationary quad-

The car is provided with a two or three

NATIONAL STEAM VULCANIZER.

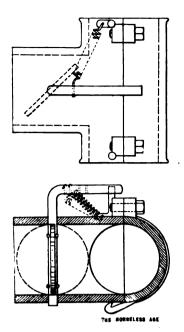

passenger roadster, four passenger baby tonneau or five passenger touring body. The equipment includes a 10 inch searchlight and generator, three oil lamps, dragon horn, tools in roll, jack, pump and tire repair outfit. The weight of the car without top and supplies is given as 1,935 pounds. In addition to this Light Six the Munch-Allen Company has been manufacturing for some time a six cylinder, 60 horse power car, which, with Bosch magneto, 122 inch wheel base, and 36x34 inch tires, sells at \$2,250. The price of the Light Six is \$2,000.

#### The National Steam Vulcanizer.

The National Motor Supply Company, of Cleveland, O., have just placed on the market a new steam vulcanizer which is adapt ed for both owners' and garage use. It is constructed with a brass shell which is to be filled one-third full of water. The heat is supplied by means of an alcohol torch with an adjustable burner. The National has a vulcanizing surface of 3 by 5½ inches, and is adapted for either tube or casing work. It can be used at home or on the road. A complete outfit is sold, packed in a small box.

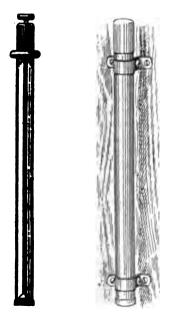

THE KEYSTONE LIGHT SIX.

STRYKER MUFFLER CUT-OUT.

#### The Stryker Muffler Cut-Out.

This device has been designed and is manufactured by C. W. Stryker, of Syracuse, N. Y. It is to be attached to the exhaust pipe, between the motor and the muffler. It consists of two malleable iron castings which fit the outside of the exhaust pipe with a gas tight fit when clamped in place over a hole in the pipe which should be equal to the inside diameter. The castings form a tee, one section of which has a butterfly valve operated by a lever to which a spring is attached to keep the valve normally closed and thus cause the exhaust to enter the muffler. The cutout serves to strengthen the exhaust pipe where it is attached and the arrangement of the castings with two hooked projections on one side and two lugs for cap screws on the opposite side provides an efficient and

STRAIGHTLINE GASOLINE GAUGE.

simple means of attachment. The cut-out is made for I, 11/4, 11/2 and 2 inch iron pipe and tubing ranging from 11/4 to 21/2 inch outside diameter by increments of 1/8 inch. The manufacturer claims the following advantages: It is easily and quickly attached, it being unnecessary to cut or disturb the exhaust pipe to do so; being fitted with a butterfly valve, carbon or mud will not prevent it from closing properly; the outlet passage being larger than the inside diameter of the exhaust pipe, there is practically no back pressure; the stops regulate the proper opened and closed positions of the valve and the spring operating the valve is sufficiently removed from

Mr. Stryker also manufactures a pedal for operating the cut-out.

the heat so as not to be affected by it.

#### The Straightline Gasoline Gauge.

This device consists of a heavy, annealed glass tube, having a valve at the lower end operated by a plunger running through to the upper end of the tube. The method of using is obvious. The tube is inserted into the tank, the plunger is depressed, and when the liquid has risen to its full height in the tube the plunger is released, whereupon the valve automatically closes. The tube is then withdrawn and the gasoline depth is indicated by a mirrorlike surface, which is claimed to be visible in the faintest light. A metal carrying case is provided, which may be attached by brackets to the dash or other part of the car.

The manufacturers, the P. R. Manufacturing Company, 621 Belleview avenue, Detroit, claim that this device is the result of a series of experiments in which a variety of principles were tried out and discarded.

## The "Aplco" Electric Vehicle Lighting System.

The Apple Electric Company, Dayton. Ohio, are now marketing their "Aplco" electric lighting system for automobiles, which comprises an automatically governed dynamo, a storage battery and a volt-ammeter. The dynamo embodies a distinct improvement over similar machines formerly used for the same purpose, which could not be positively driven from the motor, owing to the varying speed of the latter, but required a so called governor pulley, which slipped more or less to make up for variations in motor speed. The new Apple dynamo is driven positively from the motor and is controlled by a device known as a "load regulator," on which a patent is pending. This load regulator will hold the current output of the dynamo at any value for which it is adjusted, between 2 and 12

As soon as the dynamo generates sufficient voltage, an automatic cut-out connects the dynamo circuit through the volt-ammeter to a large capacity storage battery which

"APLCO" DYNAMO.

acts as a reservoir to accumulate the surplus current, and it supplies automatically the current for either the ignition or light at those times when the dynamo is under speed or at rest, and therefore not furnishing the necessary current.

The dynamo is mounted on ball bearings and has a rated capacity of 10 amperes. It is provided with a multiplier driver through which it is connected to the motor shaft, and weighs complete 24 pounds. The battery is of 6 volt, 100 ampere hour capacity.

The Apple Electric Company also supply silver plated parabolic reflectors for changing over gas headlights to electric headlights, fittings and bulbs for changing over oil side and tail lights to electric, and

ARTIZAN AUTOMATIC AIR SUPPLY OUTFIT. (See next page.)

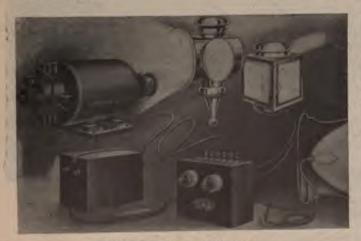

lamps designed for electric lighting only. The advantage of the latter is that they have no openings through which dirt can get into the lamp and spoil the reflecting power.

#### The Artizan Automatic Air Supply Outfit.

The Artizan Brass Company, of Chicago, is placing on the market an electrically driven, portable, compressed air outfit for inflating tires, cleaning cushions or any of the various uses to which a supply of compressed air lends itself. A 12x36 inch galvanized iron tank provides ample storage capacity, and the pressure is maintained by an automatic cut-out, which starts and stops the motor as the air consumption varies. Either alternating or direct current motors will be supplied, as ordered, and current can be taken from any incandescent lamp socket. The tank may be detached, fully charged, and is then available for use in roadside repairs.

#### The "Perfection" Lighting System.

Bishop, Delano & Co., 1463 Michigan avenue, Chicago, Ill., have brought out an equipment for furnishing electric light for automobiles, which is sold in various sets or combinations to meet the requirements in connection with different types of cars. In some of the sets a dynamo is used, and in others the current is furnished by means of a storage battery. Typical of the dynamo sets is the set No. 1, which is adopted for limousine cars. It comprises a dynamo which is either belted, gear or chain connected to the engine, a controlling box and switches. The dynamo furnishes current at 12 volts, being self regulating, electrically, so as to generate current at practically constant voltage independent of the speed of the engine. The outfit furnishes current both for ignition and for lighting two headlights of 32-40 candle power to pillar lamps, two side lamps, one tail lamp, three dome or interior lamps, one trouble lamp and one gauge light. All the lamps are 12 volt tungsten lamps, and sufficient current is generated to furnish 110 candle power at the same time.

The set No. 2 is intended for large touring cars, and is substantially the same as set No. 1, except that it includes a smaller

dynamo and only 96 candle power can be obtained at one time. The set No. 3 is a 6 volt system for small touring cars, and comprises a dynamo, controlling box and switches. Where this set is applied it is intended that the owner's own storage battery shall be used for ignition. The battery sets, of which four are being offered, all comprise a 6 volt storage battery, in two sizes, an 80

ampere hour battery being furnished for larger cars and a 60 ampere hour battery for small cars. The batteries are to be used for lighting only. The company furnishes adapters for converting gas and oil lamps to electric lamps.

Albert Dahms, general storekeeper at Neenah, Wis., has purchased a high wheel delivery wagon. A delivery of goods to a point 9 miles from the store was made in thirty-five minutes last week.

The Capitol Lumber Company has the distinction of being the first concern of its kind in Indianapolis to use motor trucks, having purchased a 1½ ton gasoline truck. This truck is being used in the delivery of lumber and building materials, apparently with much success. The company contemplates increasing its motor delivery equipment if the present experiment proves satisfactory.

PREMIER No. 1, PERFECT ROAD SCORE.

PROTESTS.

Although everything seemed to be going smoothly on the surface, underneath there was great dissatisfaction. Several parties said that Mr. Hower had "it in for them," and others said he was favoring someone else. The tour, therefore, did not end without considerable bitter feeling, and many of Mr. Hower's staunchest supporters deserted him.

Before leaving Kansas City it was made known that H. O. Smith and W. H. Vandervoort had protested the Pierces in the Glidden and Hower contests, respectively. The ground upon which the protest was made was that according to the rules the lamps of the cars should be in the same condition at the end of the tour as when the cars left Detroit. The Pierce, No. 108, had a smashed rear light and the Pierce, No. 9, had also a broken rear lamp. In addition No. 8 did not carry his lamp on the bracket for several days during the route after it had dropped off. For the present we will have to await the decision of the contest board.

The substance of the protest was as follows: Toward the middle of the tour one of the Pierce cars, No. 9, dropped and broke its rear lamp. For some time afterward the broken lamp was not carried in position. However, when it was deter-

MOLINE NO. 101, PERFECT ROAD SCORE.

CHALMERS, No. 52, WINNER OF DETROIT TROPHY.

mined that no penalty could be imposed for refastening it was replaced. The Pierce, No. 108, had its tail lamp telescoped, but the lamp was kept still in position. The protestants claim that the two cars should have been presented to the technical committee with the lamps in the same condition as when they left Detroit. In addition, the Premier Company claims that No. 9, Pierce, must, according to rules, have carried lamps during the whole tour, which it did not do for a short interval. On this ground the Premier protest the award of the prizes to the entrant of these cars. The protest was only filed, however, after the technical committee had made its report. The matter will come up before the contest board of the A. A. A. for de-

Another thing that will likely lead to complaints relates to the method of calculating the scores. Almost all the material replaced or assessed as such by the committee was for outside material. The time for labor required on all such material should have been doubly penalized, according to the rules. Clause (e) under penalties reads as follows:

(e) Time consumed in connection with such uninventoried parts and material: Two-tenths of a point for each minute or fraction thereof for each person.

In the official list of penalties as itemized in the following table this was not taken into account, as will be very evident. Only the material charges were doubled.

#### The Brighton Beach Twenty-four Hour Race.

The twenty-four hour racing tournament held at the Brighton Beach track Friday and Saturday, July 30 and 31, was won by a Simplex car, which covered 1,091 miles, thus leaving its last year's record unbroken by a margin of 86 miles. It was not necessary at any time during the race to surpass

it, and probably, in view of track conditions, any attempt to do so would have been unwise.

The contestants in the race, which was limited to cars costing over \$2,000, were as follows:

From the start at 9:05 Friday night the Fiat took the lead, which it held up to the end of the sixth round, when a collision with a fence post sprung an axle and slightly twisted the frame, inducing clutch troubles, which finally caused its withdrawal. The Haynes, which had troubles early in the race, was finally put out of the contest by a broken crank shaft. The Acme, whose troubles included a broken frame, retired in the twenty-second round. The Stearns received a setback early in the race through a broken steering knuckle, and in spite of strenuous efforts was unable to recover the lost ground. The Lozier had some trouble due to heating of a universal joint. All these misfortunes left the race to the Simplex, Rainier and Palmer-Singer cars, which kept throughout the race in the relative positions taken in the first round. The five cars which concluded the run made the following mileages: Simplex, 1,091; Rainier, 1,041; P. & S., 968; Stearns, 919; Lozier, 885. The winning Simplex car was fitted with Michelin tires and a Bosch magneto.

The police authorities stopped the race for an hour between 5 and 6 o'clock Saturday for the purpose of repairing the track, which had reached such a dangerous condition as to cause a protest by the drivers. No work on any of the cars was allowed while the rolling and sprinkling were going on.

#### Hints On the Care of Tires.

The following hints on the use of tires have been compiled by the experts of the Fisk Rubber Company, Chicopee Falls, Mass.:

Tire trouble can be classed roughly in three divisions, viz.: (1) Poor tires, (2) improper size, (3) abuse.

Of the first classification very little need be said. It is policy to buy the best regardless of price, from a reputable concern. That ought to eliminate this style of trouble.

As regards size of tires, this is one of the vital points. Air cushion is essential to the proper equipping of an automobile. It is not the thickness of the tire which counts, for a tire must have its various constructive elements in proper proportion. If thickness was the main issue, tires could be built in 4 inch sizes in the same thickness as 5 inch, but such a procedure would permit of the pulling apart and disintegrating of the tire, for it would be out of proportion. The air chamber and its size in relation to the rest of the tire have a great deal more to do with the proposition than most people imagine. One should not be afraid of getting too large a tire. That rarely happens.

It is also well to get the same size tires for both front and rear wheels, as it is far more convenient in long distance touring, when carrying extra tires of two different sizes is a burden. In event of having to replace a tire on a tour and having to buy same from a dealer, there is a much greater chance of his having one correct size in stock than two.

As for abuse of tires—the tire manufacturer gets blamed for many things that are caused by this offense. One of the commonest forms of tire abuse is lack of air pressure in tubes. Hardly one car in ten is driven around with the proper amount of air pressure in its tires. This is principally due to carelessness on the part of the driver, for if the motor is running properly the tires are overlooked until a flat one makes itself manifest.

Tires should be inflated approximately in accordance with the following table:

																											~				
Inches.																										۰			Po	uni	1s.
3	e.		'n.		.,	ē			ě	é	ă.	×			8	,		,			á	×	ĕ	ä	g			×	50		
31/2				ķ				. ,												à	×	×				ō	ĕ	a	55	to	65
4		ij,					. ,					*					٠,					×			6		ě	×	60	to	70
43/2	6,	.,					. ,	ú				,			61					è	À	ì	A		8		į,	Ġ.	65	10	75
5		.,	×			.,	.,		,			×	×	,	'n.		. ,	8	i		ä	×	٠		8		ĕ	g,	70	fo	90
= 1/4			u	ı			ı.		ı		ů,	ú	Į,	,				8		ı	u	ı	2	9			ü	ü	Re-	to.	100

A few "Don'ts" may be of value to those who wish to eliminate tire abuse. Here they are:

Don't slide your wheels by locking the brakes.

Don't go around corners on two wheels.

Don't let your clutch in suddenly so that
it "bites," causing discomfort to passengers
and injury to rear tires as well as motor.

Don't let your tires stand in oil or greasy spots.

And above all keep your tires well inflated.

#### GARAGE ITEMS

#### The Regal Garage, Detroit, Mich.

The Regal Motor Sales Company, of Detroit, was recently organized to distribute the Regal cars through the State. The company has erected the garage here illustrated and described to facilitate this work and for the convenience of Regal owners residing in the city.

The garage is located at the corner of Woodward and Alexandrine avenues, in the heart of the garage district, and close to a large residence section. The building is of brick, of the single entrance type, with 40 foot frontage and 176 foot depth. It is from the designs of Speir, Rohms & Gehrke, local architects, and is a good example of the smaller type of garage.

The showroom occupies the front of the building. It is well lighted by a window across the entire front, another at the side and a third opening on the driveway entrance. The room is panelled in Mission style and the ceiling and walls above the panelling are tinted. Mission furniture is used, and ferns and palms are employed for decoration. The floor is of mosaic, with the name "Regal" near the front, where it is noticed by anyone entering the door or looking in at the show window. A polished chassis and a car with coupé body are exhibited. The lighting for the main portion of the room is furnished by a cluster of incandescents at the centre. A "liner" light is placed above the show window for lighting the chassis. There is also a small display of lamps, speedometers and exhaust blown horns.

At the time of the writer's visit a large map of the route of the New York-San Francisco trip of the "Regal Plugger" was laid out on the front window. A picture of a car was moved along on this map from day to day, to show how fast the trip was completed. The side of the garage next the street is used for advertising purposes, a brilliant sign with full size picture of the car being painted thereon. This can be seen in the illustration.

The panelling between the showroom and the office contains clouded glass windows, which light the clerical and executive rooms. The office woodwork, walls and ceilings are finished to correspond with the showroom. The toilet rooms and coat closets open from the offices.

Sliding panelled doors between the showroom and the driveway permit show cars to be taken in and out. The stand for checking in and out is close beside the driveway, and the stockroom is next to it. The driveway ceiling is arched and is tinted the same color as the showroom, so the color effect is uniform to one looking in from the street.

The main room is lighted by eight double and one single windows on the sides, by

REGAL GARAGE, DETROIT.

windows in the rear wall and door, and by three large double skylights. Ventilation is provided by swinging shutters in the ends of the skylight monitors. The entrance is by a single sliding door at the front, and the exit is by a double swinging door opening on the alley at the rear.

The roof is nearly flat, and is supported by steel trusses. Artificial light is furnished by five gas arcs. Along the wall, about hip high, is a metal conduit, with sockets for incandescent lights about 25 feet apart. These sockets are used for attaching lights with flexible cords when washing or repairing.

The repair bench is in the rear right hand corner, and is fitted with vises and hand tools. All heavy repairing is done at the factory. At the rear left hand corner of the building a space is separated from the main room by a brick partition, and is divided into two parts. One is the wash and toilet room for the workmen, the other is the storage vault for oil and gasoline. The gasoline is stored in a 300 gallon tank underground, and is handled by the Snell hydraulic system. Oil is kept in barrels and in standard tanks.

Close beside the fuel vault is the wash rack, which is furnished with the usual swinging washer. Hot water is supplied by a Jewell gas heater and a 50 gallon tank. The building is steam heated from a central heating plant, which is close at hand. Floor radiators are used, set close to the side walls. Dry chemical fire extinguishers are used throughout. Air for inflating tires is supplied by an Allis-Chalmers electric driven compressor. The storage tank has a capacity of about 51/2 cubic feet. The air is piped to convenient points about the main room, which is a convenience that is generally much appreciated by patrons of a public garage.

## Papers to Be Read at Engineers' Meeting.

Following is a list of the papers which will be presented at the meeting of the Society of Automobile Engineers at Chicago on August 5, 6 and 7:

"Commercial Test of a Pierce Water Cooled Motor," by J. A. Luhrman and G. W. Woodward.

"Some Points in the Operation and Care of Vehicle Batteries," by H. M. Beck.

"The Wider Dissemination of Professional Knowledge and Experience," by Henry Hess.

"Possible Increases of the Weight Efficiency of Storage Batteries," by Edward Sokal, Ph. D.

"Notes on Lubricating Oil," by Frank H. Floyd.

"Energy Consumption of Commercial Vehicles," by Alex. Churchward.

"Electric Cradle Dynamometer-Method for Testing Gasoline Engines," by H. S. Baldwin

"Test of a Twenty Horse Power Franklin Air Cooled Motor," by L. R. Evans, M. E., and R. P. Lay, M. E.

#### Club Notes.

The Guilford County Motor Club was organized in Greenboro, N. C., on June 25, and the following officers were elected: Dr. J. T. J. Battle, president; F. N. Tate, of High Point, vice president; Ernest Clapp, secretary, and Dr. J. W. Long, treasurer.

An automobile club is to be organized at Waterloo, Ia., and a meeting for the purpose of organizing was called to be held at the Y. M. C. A. rooms on August 2 by a committee composed of F. A. Ferguson, G. E. Lichty and F. T. Hartman. It is said that there are between 200 and 300 automobiles owned in the city.

#### COMMUNICATIONS

## Improved Method of Balancing Single Cylinder Motors.

Editor Horseless Age:

I beg to take exception to your method of balancing a single cylinder engine, as given under the head of "Balancing of Engines" in your issue of June 16, 1909.

You say: "The proper method of balancing the moving parts of a motor is to place the crank journals on parallels, place the crank pin at the same height as the crank journals, extend the connecting rod horizontally away from the crank centre, and support the piston end of the connecting rod in this position by means of a string. Now drill the flywheels until the parts balance in this position. The method is illustrated in Fig. 2.—ED."

By this method you balance only the rotating mass (the crank pin and lower end of connecting rod) and make no attempt to counteract the vibrations set up by the reciprocating mass (the piston, wrist pin and upper end of connecting rod). At the mid-point of the stroke this gives an unbalanced vertical force (assuming a vertical engine) equal to the total kinetic energy of the reciprocating mass, or  $\frac{1}{2}$  m  $v^2$ , where m is this mass and v the velocity of the piston at this point equal to the crank pin velocity. At either end of the stroke, however, this force is o, since the velocity of the piston is then o. Thus it is readily seen that this method would give a very imperfect balance. According to the Motor Cycle, of England, the counterweight should be made equal to the rotating mass and half the reciprocating mass. Then at the mid-point of the stroke the unbalanced vertical force is just half of that in the former case (since the piston and counter-weight are moving in opposite directions), while at the ends of the stroke there is an unbalanced horizontal force of equal intensity due to the excess weight of the counter. Thus the tendency to vibrate, instead of being concentrated at two points of the revolution, is distributed evenly through four. This method is said to have given excellent results as applied to motorcycle engines. Quoting from the Motor Cycle, an easy way to obtain this balance is as follows:

"Stand the flywheels beside the weighing scales, place the piston on the pan. and block up one or other of the wheels until the connecting rod is level, weigh piston thus, and it will give us the weight of the reciprocating mass. Next, exactly opposite to and on the same radius as the crank pin, drill a small hole, one-eighth of an inch is ample, then get a piece of wire and bend the end at right

angles, so as to hang out of the hole quite freely, and on the end of the wire hang weights equal to one-half the reciprocating mass. We now want a couple of short lengths of steel rod about one-half of an inch in diameter; these are to be laid on two benches parallel to one another and very carefully leveled. When everything is ready place the flywheels on them with a main shaft on each rod and weight hung out of small hole. It will be easy now to see which side is too heavy, and holes may be drilled there until the flywheels remain in any position whatsoever." N. FLOYD.

#### Flexible Metallic Tubing.

Editor Horseless Age:

We notice in your description of our flexible metallic tubing in the July 14 issue of The Horseless Age that you say the tube may be used for exhaust pipes and hot air collecting devices for carburetors, but we feel sure that the tubing you have seen used for this purpose is not ours, but a tube of a considerably thinner wall, made from a single coil of flat brass and an asbestos packing.

The Almond tube is made from two coils of wire, one coiled outside the other. The inner coil is a spring tempered wire round in cross sections and coiled close, with no opening between the convolutions. The outer coil is a tinned soft iron or brass wire, half round in cross section, wound with the flat side over the spring, and forced with considerable pressure in between the convolutions of the spring, thus making a tight joint. It will stand twenty-five (25) pounds pressure.

If this tubing is used for conveying exhaust gases, the high temperature draws the temper of the inner coiled spring, softening the wire sufficiently to cause leaks, and also melts the solder used in attaching the fitting, so that it is impossible for us to recommend it for this purpose. It is most useful as a conveyor of grease, oil and gasoline.

T. R. ALMOND MANUFACTURING Co.

## To Improve the Cooling System of An Old Car.

Editor Horseless Age:

I am building a new radiator and water circulation system for an old car equipped

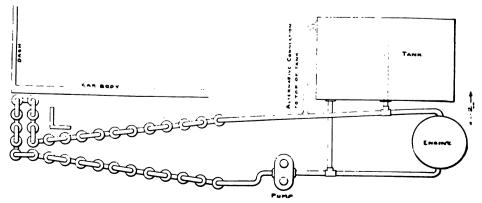

with a single cylinder, horizontal, four cycle, 8 horse power motor under the body The cylinder dimensions are 5x6 inches. I want to ask a question in regard to this circulating system, as to whether there is any advantage in using the tank which forms part of the system. It is quite a large tank, separate from the radiator. In an article I saw in a back number of THE Horseless Age it is advocated to use the tank as a reservoir connected with the circulating system. The idea is entirely new to me, but if it is practicable I wish to embody it in the circulating system which I am planning, as it would do away with the only weak or undesirable feature of the design.

The accompanying sketch shows the way I plan to arrange the cooling system. I would like to know whether there is any other possible arrangement of the parts (tank, pump, engine, etc.) that is preferable, and also whether I can improve on the shape and type of radiator.

First as to the circulation through or past the tank. The accompanying sketch is intended to show only the locations of the parts, the relative distances between them, and their relative heights, and to give the rise or fall of pipes. Some of the inclinations are exaggerated, particularly those to and from the engine. The pipes, unfortunately, are quite long and have many bends in them, but the worst ones cannot be eliminated.

Originally the circulation was from the top of the engine to the tank, to the radiator, to the pump and back to the bottom of the engine. The water was always boiling and the motor overheated, and I concluded that some advantage could be gained by changing the order of circulation as follows: From top of engine to radiator, to tank, to pump, to bottom of engine. Can this order of circulation be improved?

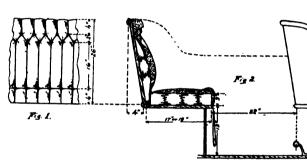

Now, as to the circulation through or past the tank. My objection to the first plan I laid out was based on the curved pipe which has to connect the radiator to the tank if it is to enter the tank on top, avoid the crank case, etc. This is the only bad feature of the design, the arrangement of all the other parts tending to aid thermal or gravity circulation. I see that in the sketch reproduced from one of your back numbers the pipe enters the tank below the top. I would like to know whether

this is practically possible, as if I can go from the radiator to the pump direct I can avoid this long upwardly bent pipe, though I am still compelled to make an upward curve.

The other question I want to ask is, What sort of radiator is best to put in the available space, which, as shown by the sketch is 25 inches long by 71/2 inches deep, with an upper front L 434x31/3 inches? I would greatly like to use this L space, but I know of no way by which to accomplish it. My present plan is to build a radiator myself of a continuous coil of 34 inch flanged copper tubing, the horizontal length to be 26 inches, making a total length of pipe of 41 feet, arranged triangularly as shown. This promotes thermal or gravity circulation and avoids bumping of the radiator against the axle, due to unusual compression of the springs. If I were to put in more layers of pipes some of the pipes would come over the front axle; and, besides, the radiator would be a compact mass, and the air circulation through it would be retarded. Can the 434x31/2 inch space be utilized? The pipe from the en-

gine must enter at XA as now, that is, below the frame. Water can only be gotten to the top of the 43/4x3½ inch space by raising it 3½ inches either in the radiator or without it. Can either be done with advantage? Could the 43/4x3½ inch space be used by a

SEAT CONSTRUCTION.

regular cooler construction arranged vertically, or in any other way?

Can you advise me whether the form of radiator tubing in which separate copper fins are soldered to the tube or the spiral copper fin on copper tubing is the best? If the spiral tubing is the best, where can I purchase it? My sketch shows 26 lengths, making a total of 41 feet of 134 inch fin tubes spaced as closely as possible. The spiral flange tubes would probably have flanges of smaller diameter. In that case would it be preferable to use the number of tubes indicated in the drawing, with air spaces in between, or to place adjacent tubes as closely as possible, using an increased length of tubing, perhaps 50 per cent. more? FCF

[We would advise that you connect the tank in parallel to the radiator by running a pipe from the pump to the bottom of the water tank, and a pipe from the upper pipe to the engine jacket nearly to the top of the tank. The latter pipe may extend up inside the tank or connect to the tank near the top outside. This will greatly simplify the piping.

It is quite possible to use the 43/x3/2 inch space, as you can run your coil up into it, then down again and then back. We do not know whether the plane or

spirally flanged tubes are best, as no comparative tests have been made to our knowledge.—ED.]

#### Comfortable Seats.

Editor Horseless Age:

The comfortable seat in automobile bodies has been neglected to some extent. The inventors of the earlier machines generally fitted them with freakish designs of bodies, they having had no experience in this line of the business. The design of carriage or automobile bodies should be left to the expert body designer. This is an art by itself, which can be acquired only by very long experience. But no matter what may be the shape of the seat, it is largely left to the carriage trimmer to produce a comfortable, easy riding seat.

There are standard dimensions of seats to some extent, which are now and then changed to suit circumstances. The more nearly vertical or straight the back of the seats are the shorter the body can be built—a leaning back necessitates more foot room and making the body longer.

The most comfortable as well as best ap-

pearing back is the "pipe tufted" one, Fig. 1. This style of back conforms best to the outlines of the human body. A seat constructed after the lines and measurements of Fig. 2 will make a compromise seat for long or short drivers, the back being moderately inclined. For a special machine for touring the back should be inclined somewhat more. An adjustable arrangement to suit the individual would be advisable, and could be made by fastening the lower part of the back to the rear end of the chassis and have the chassis on a short slide, say 6 inches. When the chassis is pulled forward it will incline the back more.

Reverting to the seat shown in Fig. 2, the springs must be placed in the right position, and the upper roll should be made firm, but at the same time soft. The best obtainable horse hair should be used for that purpose or it will not hold its shape.

The cushions should be built up of a spring box covered with a layer of horse hair and not tufted. Across the front, on top of the cushion, a 3 inch roll will give a good support under the knees. The foot brace must be placed in the proper position, or, if possible, be made adjustable. According to carriage practice a straight or nearly vertical back will give a natty appearance to the body, and for short rides,

as in society drives, this is the conventional type. It is advantageous to the appearance of ladies' dresses, and the sitting position is more graceful. The inclined seat gives more rest to the human body, as it distributes the weight over a larger area and permits freer circulation of the blood; hence avoids fatigue. All mail or stage coaches have inclined seats and box spring cushions.

JOSEPH LEDWINKA.

#### Friction Coefficient for Use in Calculating Cork Insert Clutches.

Editor Horseless Age:

Kindly inform me in your valuable paper about the following:

What friction coefficient is safe to use in calculating a cork inserted cone clutch, surfaces oiled or dry? Which of the two, oiled or dry, is preferable?

[We referred this question to the National Brake and Clutch Company, Boston, Mass., who inform us that the following are the friction coefficients for various frictional materials:

#### COEFFICIENTS OF FRICTION.

New leather on dry metal, say	. 23
New leather on oily metal, say	. 15.
Old, dry, hard or charred leather on oily metal.	. 08
Leather with cork inserts on dry metal	.35
Leather with cork inserts on oily metal	. 32

Assuming that a designer proposes to take .15 as the coefficient of friction for a leather faced cone the company advise that he take .20 as the basis of calculation for a leather faced cone having an angle of face of 12½ degrees and equipped with cork inserts, and that he reduce his spring pressure approximately 33½ per cent. They do not recommend that a leather faced cone with cork inserts be run in oil, but advise lubricating it from time to time with ordinary cylinder oil if it grabs too harshly; otherwise, allow it to run dry.—Ep.]

#### The Austrian Automobile Industry.

The Austrian Automobile Manufacturers' Association has recently issued its year book for 1909, entitled "The Austrian Automobile Industry and Its Resources." The book contains no less than 400 pages, and is intended to serve both the purpose of publicity for the industry, and as a work of reference. The Austrian Automobile Manufacturers' Association is only of relatively recent origin, having been organized on April 15, 1907. The members are divided into groups according to the number of their employees, with corresponding voting powers. Automobile manufacturers are divided into five groups, employing up to 30, up to 100, up to 200, up to 500, and above 500 men respectively. The accessories' manufacturers are divided into only two classes, viz., those employing up to thirty, and those employing over thirty men. Dealers are also admitted to membership, and each has one vote. The association at present comprises ten automobile manufacturing firms, and twenty-seven firms engaged in the manufacture of automobile accessories.

## Commercial Applications.

## The Taxicab Business in Philadelphia.

By H. J. D.

The taxicab business in Philadelphia, Pa., is practically controlled by three companies. viz., the Bergdoll Motor Car Company, the Pennsylvania Taxicab Company and the Quaker City Cab Company. In addition to these a few individual owners operate taxicabs. Philadelphia offers a very promising field for taxicab operation, inasmuch as large first class hotels are scattered throughout the city, and, besides, Philadelphia is the scene of numerous conventions and reunions of lodges and secret societies. While there are a large number of taxicabs in service at the present time it is quite obvious that in a year there will be twice as many.

THE BERGOOLL MOTOR CAR COMPANY, with offices and garage at the corner of Broad and Wood streets, is at the present time operating thirty cabs. These are all Thomas cars of the landaulet type. The company are now building their own cabs, to be known as Bergdoll "Thirties." These are being built right on the premises, and will supplant the cabs now in service when completed. Fifteen will be put on the street early in September, and thirty-five more before the end of October.

One of the features of the Bergdoll cab is that the motor and transmission are one unit, which is very easily removed by taking out four bolts. When the bolts are removed the motor and transmission may be dropped, after which they may be repaired or adjusted and then placed back on the frame without disturbing any other part of the car. Another notable feature of the Bergdoll cabs will be the fact that for each one there will be two bodies, a closed body for winter use and a touring body for summer use. The closed body is of the brougham type, roomy and airy. It is upholstered in plain leather, so that it may be handily washed and cleaned. The floor of the body is laid with linoleum, which also covers the lower half of the doors. The back cushions are of tufted leather. The doors have three hinges. The tourng body is also of special design. All the Bergdoll cabs will carry a speedometer.

The Bergdoll Company have no regular stands, most of their business being done direct from the garage, orders being received by mail and 'phone. They also rent out the cabs by the day, week or month.

Pneumatic tires are used, with demountable rims, both of Fisk make and maintained under contract by the Fisk Tire Company.

The rates are 50 cents for the first mile, 40 cents for each additional mile, and 20 cents a mile to call where desired. The

same rate is charged for four passengers as is charged for one. The taximeters are driven from the rear wheels, while the front wheels are equipped with odometers. By this method one must tally with the other, and in the event of their not tallying an average is taken which is accepted as the correct distance.

The Bergdoll Company have a novel plan for the remuneration of their operators. The car is leased to the driver each day, and he is allowed a percentage of the entire day's receipts. By this system the firm is immune from any legal liability due to negligence or carelessness on the part of the driver.

THE PENNSYLVANIA TAXICAB COMPANY,

located at 1407 Locust street, are at the present time operating twenty-one taxicabs. This concern also has its offices and garage in the same building. The cabs now in this service are two cylinder Autocars and cars assembled by the company themselves, which are equipped with Continental motors. The number of cabs will be doubled before the end of the year, and Autocars will take the place of the assembled cabs. The taximeters are on the rear wheels now, but will all be changed to the front wheels.

This company controls probably the best stand in the city, in front of the Bellevue-Stratford Hotel, the largest in the city and one of the finest in the world. It accommodates the élite set from all parts of the country when visiting Philadelphia. This stand alone keeps a good portion of the cabs working all the time. In addition to this they have a large select list of regular patrons, who order a cab when they need it by 'phone.

On the Autocar cabs Fisk detachable tires are also used, and on the others Diamonds of the regular clincher type.

The rates are 50 cents for the first mile, 40 cents for each additional mile and 20 cents a mile to call, outside of a half mile from the City Hall.

The company also hires out five Packard touring cars for special service or country trips. These are not, however, equipped with taximeters and are charged for by time. All repairs to both the touring cars and taxicabs are made right in the company's shops.

The operators are paid a commission on the net receipts, but the company assumes all liabilities for accidents and personal injuries sustained at the hands of a driver.

The busiest hours on week days in the summer are from 11 a. m. to 2 p. m. and after 6 p. m. On Sundays the cabs are busy all day, and also in the evening.

The officers of the Pennsylvania Taxicab Company are Joseph T. Kinsley, president; Paul Samorelle, vice president; W. C. Wilson, secretary and treasurer; George W. Close, assistant secretary and treasurer.

THE QUAKER CITY CAB COMPANY, who also operate the Taxi Service Company, have two garages, one at 1211 Vine

street and the other at 305-7 North Twelfth street. The company are at present operating thirty-five American Locomotive cabs. They will increase this number by twenty-five on September 1. They have hacking stands at the railroad station and at several of the important hotels.

Their cabs are not equipped with taximters, and their charges are \$4 per hour. If the cab is used less than one hour the occupants are charged proportionately. Quick detachable pneumatic tires are used, and Stepney spare wheels are carried on all the cars. The company have no maintenance contract with either the car or tire manufacturers and do all their own repairing at their own shops.

The chauffeurs are all paid a regular weekly salary and all gasoline, oil and parts are furnished them by the company free of charge. The busiest hours on week days during the summer are from 2 to 6 p. m.; in the winter from 4 to 9 p. m., and on Sundays from 11 a. m. to 11 p. m. The superintendent claims to have no trouble in securing good drivers. The latter must supply their own uniforms.

The Quaker City Cab Company have started negotiations for a new home at 1207 to 1217 Vine street. A four story brick building at that address is to be used as a garage and offices. The first floor will be used for the company's business and the upper stories for storage purposes. The building was designed by the engineer of the American Locomotive Company, and it is estimated that the cost will be about \$100,000. The structure will be known as the Jarvis Building.

The cabs that are being operated by individual owners are of various makes, and in the majority of cases no regular systems of operation are employed. In the State of Pennsylvania no hacking license is required to run a taxicab, nor are there any special ordinances governing them. A taxicab has only to carry an ordinary automobile license tag and comply with the regular automobile laws.

#### Commercial Notes.

The Taxicab Company, of Nashville, Tenn., is reported to be doing a good business, and will shortly place three additional cabs in service.

An automobile service will shortly be inaugurated between Bridgeport and Upper Stepney, Conn. A large bus will be used, and four round trips will be made per day.

Frank Huffman, Middletown, Ohio, will shortly place in service a motor bus made by the White Company, of Cleveland, Ohio. Mr. Huffman will operate the car over a belt line in the city.

The Maine Summer Resort Company, which is developing Idlewild Park at Cundy Harbor, Me., will shortly inaugurate an automobile stage service. A combination vehicle for carrying either nine passengers and baggage or fifteen passengers without baggage has been purchased.

# New Indianapolis Ordinance.

Ordinances requiring the registration of automobile and motorcycle drivers and operators, and also further regulating such vehicles, have been passed by the Indianapolis city council, signed by Mayor Bookwalter and are now in effect.

Prospective drivers must appear before the board of public safety, giving their names, addresses, ages and qualifications for driving. If such information is satisfactory the board will authorize the city controller to issue a license upon payment of a \$1 fee, the license to be good for one year. Changes of address must be reported within five days, and for a third violation of any automobile ordinance or law the judge of the police court is given power to revoke a license. A workhouse sentence is provided for attempting to drive an automobile or motorcycle after a license has been revoked.

Another measure requires the use of mufflers, prohibits the running of machinery when cars are left unattended, requires the display of lights on front and rear when cars are left standing in the streets at night, and fixes the minimum age limit of drivers at seventeen years. A measure is pending in the council to increase the police motorcycle corps from three to five men, the corps being used in running down violators of the speed laws.

# Owner Protects Reckless Driver.

Fred A. Cornell, a Los Angeles automobile dealer, was arrested July 25 charged with being an accessory after the fact in the killing of Mrs. Dora Feller ten days previous by his driver, Carl Fisher, though Cornell was not in the car he owned at the time his driver struck the woman. Because he failed to turn over to the police information about the guilty party, and because, after his arrest, he assisted the driver in making his escape, Cornell was held under \$15,000 bail, and will be tried on a charge of manslaughter, with a penitentiary sentence in prospect on account of the state of public sentiment aroused by the numerous fatal accidents caused by teckless drivers.

The victim was killed while crossing the street in front of her residence at night. The machine was going at high speed on the wrong side of the street, without lamps, and the driver succeeded in escaping without having his identity established or the number of the machine ascertained. The rewards of \$650 offered by the Motorists' Protective Association and the police led to his identification, through the remark of a woman dropped on a pier at a nearby beach resort and overheard by an officer on his

vacation. The woman boasted of being able to earn \$650 by informing the authorities of the name of the man who killed Mrs. Feller.

When Cornell, the owner of the car, was arrested at his garage he asked for time to pay off his men, and made use of the opportunity to warn the driver, who was in the shop, and who fled at once. When he realized the consequences of aiding the man to escape Cornell confessed in an effort to clear himself. He gave the names of the women who had been in the machine at the time of the accident, and these women related that Fisher, after killing the victim, sped away, stopped at a distant corner, wiped the blood from the machine, removed pieces of the dead woman's dress and burned them. The owner of the car was told of the accident the next day, and at once sold the automobile.

# Proposed Detroit Licensing Ordinance.

The committee on ordinances of the Detroit common council has approved an ordinance which provides for the licensing of all drivers of automobiles, except owners, who are practically immune from city regulation under the State law. John Gillespie, representing the Detroit Motor Club, and Robert K. Davis, representing the Detroit Automobile Dealers' Association, attended the hearing. Both appeared anxious for an ordinance which would tend to do away with speeding. Mr. Davis wanted the ordinance drawn so that the immediate family of the owner could operate the car without a license. Mr. Gillespie suggested that while all drivers be licensed only paid drivers be required to wear a badge.

As approved by the committee the ordinance requires that all drivers pass an examination before they receive a license, and that all drivers of cars must be sixteen years old or over. Visiting drivers will be allowed three weeks before being required to take out a license. It is proposed to draft an ordinance defining speed limits and penalties for infraction at an early date.

# Legal Notes.

Joseph Warren Smith, who tried to purchase an automobile from the Fisher Automobile Company, Indianapolis, with a fraudulent check, has been returned to the Indiana Reformatory to complete an unexpired sentence. After his arrest it was found he was on parole from the reformatory on another charge.

The decision against Herbert B. Tompkins, of Buffalo, N. Y., who was fined \$10 by Justice of the Peace Eiss for taking a turn at more than 4 miles per hour, was reversed by Judge Taylor in the County Court at Buffalo on July 28. The curve around which Mr. Tompkins drove when he was arrested was shown by surveyor's maps to be no more than 11 degrees, and Judge Taylor held that such curves were not included in the provision of the law.

which requires the speed to be reduced to 4 miles an hour in driving around turns in the road.

The police of Pittsburg, Pa., have collected the names of automobile owners whose cars are not provided with drip pans, and which do not comply with the city ordinance in other respects. The names of offenders will be presented to an aldermanic committee, and it is likely that warrants will be issued against them.

City Collector Magerstadt of Chicago has submitted to Corporation Counsel Brundage a list of automobile owners who have failed to pay taxes due on their machines since May I. The list will be turned over to City Prosecutor George H. White, who will begin suit for the collection of the taxes in the municipal court.

John M. Satterfield, president of the Buffalo A. C., and Herbert A. Meldrum, of the same club, appeared before the committee on ordinances of the Buffalo city council on July 22 to urge the passage of a new ordinance requiring all vehicles on the streets at night to be equipped with lights both in front and rear. They describe Delaware avenue as a most dangerous place to drive in on a dark night, and in return for the concession of the universal lighting provision they offered to accept a prohibition of all objectionable forms of warning signals on automobiles.

### Milwaukee Considering Wheel Tax.

The Milwaukee common council is considering an ordinance introduced by Alderman Eric Cramer Stern (its youngest member) providing a wheel tax for all motor vehicles, carriages, delivery wagons and other horse drawn vehicles, excepting bicycles, the proceeds of which tax are to go into the special street repair fund. The motor vehicle tax is graduated from \$5 to \$12, according to horse power, and horse drawn vehicles will be charged from \$1.50 for single rigs to \$15 maximum. "There is no reason," said Alderman Stern, in introducing the measure, "why the streets should not be repaired at the cost of the people whose vehicles and operations injure them."

# Parry Auto Company Settled.

A three year lease on the former plant of the Standard Wheel Company, of Indianapolis, has been taken by the newly organized Parry Auto Company, which concern is equipping the plant with the necessary machinery. The Parry Auto Company, which expects to have its first car completed about August 20, has an authorized capitalization of \$1,000,000. David M. Parry, former president of the Parry Manufacturing Company, is president of the new company. Others interested are Warren D. Oakes, former sales manager of the Parry Manufacturing Company; Maxwell O. Parry, a recent graduate from Yale University; William C. Teasdale, Jr., of St. Louis, a manufacturer, and Addison J. Parry.

# E-M-F Company Buys Drop Forging Plant.

Following the purchase by the E-M-F Company of the De Luxe plant in Detroit last week comes the announcement that the same company has also bought the entire property of the Western Malleable Steel and Forge Company, adjoining the De Luxe property. This plant, originally devoted to the making of malleable steel castings, has during the last three years followed the trend of demand and gone into the drop forging line on a large scale-so much so that the forging department has of late constituted the greater part of the business. Dropped forged parts, crank shafts, front axles, spindles, gear blanks, connecting rods, and, in fact, all the principal parts of the motor are now made in this plant, and several of the largest automobile manufacturers are said to be its customers

The possession of its own drop forge plant will obviate the chance of delay in deliveries of parts, which is a most important matter to a manufacturing concern operating on a large scale.

Besides the drop forging plant the E-M-F Company has also bought the plant of the Monroe Body Company in Pontiac, about 20 miles from Detroit. From this plant a great many bodies have been supplied to automobile factories the past several years. It is reported that about \$500,000 was paid for the two plants.

# The Mason Motor Car Company Removal.

Senator Maytag, principal stockholder of the Mason Motor Car Company, of Des Moines, Ia., has rejected the offers made by the Greater Des Moines Committee in their efforts to retain the motor car works in that city, viz., a free site of 40 acres and the placing of \$150,000 stock of the company among local investors, and has issued a statement to the effect that the company will be removed to Waterloo, Ia., in the near future. F. F. McElhinney and William Galloway, prominent Waterloo capitalists, have secured an interest in the Mason Company. It seems, however, that the removal still hinges upon certain conditions made to the Chamber of Commerce of Waterloo. If the latter body can meet these conditions the removal will take place.

# Plans of Cole Motor Car Company.

The Cole Motor Car Company, recently organized in Indianapolis, Ind., will occupy the property formerly used by the Overland Auto Company, and will manufacture a car known as the Cole Thirty, which is to be made in roadster, demi-tonneau and touring car types, selling at \$1,400, \$1,450 and \$1,500, respectively. The company, however, intend to add a smaller car, with a block type of motor, to sell at \$900 to \$1,000. The officers of the company are J. J. Cole, president; S. J. Juqua, vice pres-

ident; J. F. Morrison, treasurer, and Lester McCullough, secretary. The company are at present located in a four story building at New York and Agnes streets, which will be used as the painting and trimming department after the new plant has been occupied.

# Motor Mail Delivery in Indianapolis.

Four gasoline automobiles are now used by the Indianapolis post office. Ultimately it is the hope of Robert Bryson, postmaster, to use automobiles exclusively for the collection of mail and partially in the delivery of mail. The cars are used for carrying large bundles of mail to convenient points of carriers' routes, for delivering large bundles of mail to business houses and manufacturing concerns, and for collecting from street mail boxes.

# Touring Car Stolen.

The 1909 model Cleveland roadster owned by C. R. Manville, a Milwaukee member of the H. W. Johns-Manville Company, was stolen on July 15, and efforts of police, Pinkertons and representatives of the insurance company have failed to find it. The motor number is 3081, car number 2043; 45 horse power motor, 36 inch wheels, finished in drab.

# A New Wind Shield Company.

The Auto-Automatic Wind Shield Company has just been incorporated in Detroit by David N. Harper, C. F. Green and H. H. Seely. The capital stock is given as \$5,000, half of which is represented by physical assets.

# Tester Killed in Joy Ride.

John Swanson, a tester for the Pope Manufacturing Company, of Hartford, Conn., was fatally injured in an automobile accident at Windsor, Conn., on July The car was owned by James H. Knight, president of the First National Bank of Hartford, and was driven by his chauffeur, Michael Sullivan. According to eyewitnesses it went into a curve at about 60 miles an hour, skidded and crashed into a pole. Swanson, who was occupying a seat in the tonneau, struck the pole and died at the hospital shortly afterward. A young woman, who occupied the seat beside him, and the driver, Sullivan, were uninjured.

# Long Island Motor Parkway Matters.

The Long Island Motor Parkway Company has placed a mortgage for \$1,000,000 on its parkway property at Mineola, L. I., with the Windsor Trust Company of New York City, to secure a bond issue of like amount. The bonds will run twenty-five years and bear interest at 4½ per cent. It is said that the work of completing the parkway will now be pushed actively. The

completion of the parkway is being interfered with by a recent decision of the Nassau County board of supervisors not to permit the crossing of the parkway with Jericho turnpike at Bevel Hill, near Mineola. The matter will be taken to court.

# Garage Fires.

Four people were seriously injured by a gasoline explosion in the garage of the Berwin Auto Company in Allentown, Pa, on July 24. The explosion is supposed to have been caused by spilled gasoline being ignited by the headlight on the car of Marion Hertzog, of Kutztown.

A loss of about \$12,000 was sustained from a fire in the garage of Persons & Wonson, Worcester, Mass., on July 27. The fire was caused by the explosion of an electric light globe, which ignited gasoline that had been spilled on the floor. A chauffeur near the scene of the explosion was seriously injured.

# Overland Company Erects Three New Buildings.

The Overland Automobile Company, of Indianapolis, Ind., will spend about \$40,000 this year on enlargements to its Indianapolis plant, at Oliver avenue and Grover street. A building permit for a \$10,500 building, for an assembling and upholstering department, was issued on July 23, and two more buildings will be erected before the fall. These latter two buildings will house an enameling department and a power plant, respectively. The power plant will cost in the neighborhood of \$20,000. The buildings will be constructed of heavy timber and corrugated steel.

# Another Implement Company Enters Automobile Field.

The Kingman St. Louis Implement Company, St. Louis, Mo., have entered the automobile field, and have taken the Rambler agency in southern Illinois, eastern Missouri and Arkansas. The Kingman Company is said to be one of the largest in its line in the country, and does a business of about \$1,000,000 a year. L. N. Burns, manager of the Kingman St. Louis Implement Company, will have direct charge of the Rambler business in the above mentioned territory, and he will be assisted by J. H. Ramsden.

# Motorcycle Mail Delivery in St. Paul.

Postmaster Edward Yanish of St. Paul has made application to the Department at Washington for permission to purchase two 5 horse power gasoline motor tricycles for the collection of mail in the city. The machines will be specially built, and cost between \$300 and \$400 each. Some experiments were made with one such machine several months ago, and proved entirely satisfactory, and the only drawback to its use that can be foreseen at present is difficulty with the heavy snow in winter.

# MIN OR MENTION

Fred J. Willman and Martin Engseth have established the Minot Tire Company, Minot, N. Dak.

The Amos-Pierce Auto Company, Syracuse, N. Y., have recently made extensive improvements in their showrooms.

The Heitger Carburetor Company, Indianapolis, Ind., state that they will reorganize with ample capital to extend their business.

The Elkhart Motor Car Company, Elkhart, Ind., are about moving into their new factory, and will start an aggressive campaign in the fall.

The Couple Gear Freight Wheel Company, Grand Rapids, Mich., are bringing out an electro-gasoline truck with a four cylinder "gas" engine as prime mover.

On Wednesday of last week the Model Automobile Company, of Peru, Ind., broke ground for a building 400x75 feet. A large crowd of business men attended the ceremony.

D. M. Parry, who, as mentioned in a recent issue, has organized a company to manufacture automobiles, is negotiating with Connersville, Ind., citizens regarding locating there.

The Trenton Rubber Company, of Trenton, N. J., has changed its name to Thermoid Rubber Company, Thermoid brake lining having become its principal article of manufacture.

The Hawaiian Pineapple Company, of Honolulu, H. I., are using an 18 horse power Franklin runabout in connection with work between a cannery at Iwilei and the fields at Wahiawa.

We have a copy of the Circular of Information of the College of Engineering of the University of Illinois, published by the university at Urbana, Ill. The circular covers the university year 1909-10.

T. J. Kehoe, of the Dayton, Ohio, Automobile Supply Company, has constructed a new car, and is making arrangements for manufacturing it under the name of the "T. J. K. Special" in Fort Wayne, Ind., his former home.

Gray & Davis, the lamp manufacturers of Amesbury, Mass., have let a contract for the addition of a second story for the north wing of their present factory building. This will give them 25,000 square feet additional floor space.

The property of the Walter Automobile Company, Trenton, N. J., was sold on July 29 for \$83,000 to Judge George W. Mc-Pherson, representing the bondholders. The amount of the bonds, including interest, is about \$244,000.

The Austin Automobile Works, of Grand Rapids, Mich., may be removed to Fort Wayne, Ind. W. S. Austin, manager of the company, recently visited Fort Wayne, and is said to have been very favorably impressed by the city.

The Westinghouse Machine Company, Pittsburg, Pa., recently closed a contract for building 1,000 automobile motors, and it is reported that the company expect to go into this line of work extensively.

A permit has been granted to Albert Kahn for the erection of a four story factory of reinforced concrete for the Packard Motor Car Company. This factory will cost \$60,000, and is located one block south of the main factory.

The Empire Tire Company, Trenton, N. J., have recently opened a direct branch in Philadelphia, at the corner of Broad and Wood streets, in charge of E. B. Richardson, who was formerly for a long time connected with the Pierce Bicycle Company.

Ground has been broken for the new addition to the plant of the Federal Rubber Company, of Milwaukee, at Cudahy, Wis., a suburb. It will be three stories high, of solid brick construction, and will be devoted mainly to the tire department.

V. H. Kreigshaber, of Atlanta, Ga., is planning to begin the manufacture of automobiles, and to have his first machines ready in time to exhibit at the Atlanta show next fall. Runabouts and light touring cars ranging in price up to \$1,400 are to be made.

The Motor Company, Philadelphia agents for the Premier cars, have arranged an endurance run from Philadelphia to Cape May and back for Premier owners only, to be held Saturday and Sunday, September 11 and 12. A 2 gallon solid silver punch bowl is offered as a prize.

- John Galvin has purchased a building site at Long Island City, N. Y., on East avenue, between Thirteenth and Fourteenth streets, for \$20,000. Mr. Galvin intends to erect on it a four story reinforced concrete factory building in which to manufacture automobile specialties.

According to a report from St. Louis Jerome E. Harrington, a banker of Watonga, Okla., has closed contracts for 2,000 cars with manufacturers in Detroit and Indianapolis. He has secured the distributing agency for these cars for four States, and will have depositories in Oklahoma City and Dallas, Tex.

The Luce Manufacturing Company, Dalton, Mass., are installing machinery to manufacture a device to control the headlight of an automobile from the steering wheel, so that the light will be kept in the exact direction in which the car is traveling. Any make of car can be equipped with the device in twenty minutes.

We have received a copy of a pamphlet entitled "American Universities, American Foreign Service and an Adequate Consular Law" issued by the National Business League of America, Chicago. It relates to the facilities offered young men by various universities for preparing themselves for the consular service, gives a resolution adopted by the association disapproving of the plan to establish a national consular

school, and discusses "an adequate consular law."

According to the quarterly report of the A. L. A. M. the Cadillac Motor Car Company has done a larger volume of business in the last quarter than in any previous one.

The automobile owners of Webster City, Ia., who are now said to number seventy-five, are planning to ask the city council to be allowed the exclusive use of Superior street for two hours each day, one hour in the morning and one in the evening. The street would be used as a speedway for demonstrations, etc.

John W. Bergers, who recently retired from the Bergers Automobile Company, of Omaha, Neb., has organized a new company, known as the Western Automobile Sales Company, with offices and salesrooms in Omaha and Kansas City. The company will have a capital stock of \$50,000, and will do a wholesale business only.

A. H. Hopkins, formerly manager of the Cartier-Chapman Company, of Ludington, Mich., has secured control of a number of new inventions and embodied them in an automobile which he plans to manufacture in Ludington. The car is to be known as the "Utility," and is of the convertible type, making it available both for business and pleasure purposes.

The Fairview Motor Company, of Detroit, Mich., to whose organization by members of the Chalmers-Detroit Company we referred in our last issue, plan to erect a \$150,000 practically fireproof building on a tract recently purchased and located directly west of the Chalmers-Detroit plant. The company plans to manufacture taxicabs, trucks and delivery wagons.

A temporary receiver has been asked for the Motor Car Company of New Jersey, with headquarters at Newark. It is claimed that the concern is solvent, and that the proceeding is due solely to a change in the management, resulting from disagreement between the principal stockholders. The application was made by creditors of the concern, with the acquiescence of the managers, it is said.

A. M. Chase, of the Chase Motor Truck Company, Syracuse, N. Y., recently made a trip from that city to Whitefield, N. H., in a new Chase combination surrey and business wagon, which has just been completed by the company, and of which 400 are to be built this year. Mr. Chase stated that he had made the trip to Whitefield without mishap, having covered 107 miles the first day and 110 the second.

A meeting of local business men was recently held in Waukesha, Wis., at which a project to organize a company for the manufacture of automobiles, especially commercial vehicles, was discussed. It was decided to give financial encouragement to the project as soon as a competent man can be secured who will invest several thousand dollars and assume the management of the company. A capital stock of \$50,000 was suggested.

# Garage Notes.

L. G. Adolphson will open a garage in the Schweiger cabinet factory in Springfield, Minn.

The Russell Motor Co. has bought the plant and stock of the Duluth Motor Vehicle Co., Duluth, Minn.

Ground has been broken for the new garage of James Boyd in Norristown, Pa., on Main street, near Markley.

The Quaker City Cab Co., Philadelphia, Pa., are

The Quaker City Cab Co., Philadelphia, Pa., are receiving bids for a large garage to be erected on Vine street, west of Twelfth.

F. G. Hartman, of the Hartman Motor Car Company, of Omaha, Neb., has opened a repair shop in Huron, S. D., at 1150 Fourth sereet.

Andrew Reis, of Green Bay, Wis., has been appointed district agent for northeastern Wisconsin of the Moline. He intends to build a garage.

Another story is to be added to the Park Garage, Twenty-second and Spring Garden streets, Philadelphia, Pa. The work will probably be completed by September 1.

Howarth & Taylor have opened a garage at 172 Pacific avenue, Brocklyn, New York, where special attention will be given to repairs. They will also conduct a taxicab service.

H. K. Smith has purchased the Beckwith Garage from Everett and Orville Beckwith at Mt. Pleasant, Ia., for \$4,000. Mr. Smith intends to do an extensive livery business.

Robert Raymond, of Eau Claire, Wis., for several years foreman of the repair department of the Tanberg Auto Co., of that city, has opened a repair shop and garage at Bloomer. Wis.

George Pregler, Jr., of Madison, Wis., is building a large public garage and repair shop on West Johnson street. The dimensions are 30x120. It will be of brick construction, one story high.

Frank R. Bryant, who has secured the agency for Chalmers-Detroit and Hudson cars at Water-loo, Ia., will shortly begin work on a new garage building 140 feet long, and either 40 or 60 feet wide.

Fred W. Jackson is erecting a 30x100 one story garage in Holland, Mich., on Seventh street just east of the river. The building will cost about \$3,000, and will be ready for occupancy about August 15.

Chas. Hill has opened a garage and repair shop at 15 North Lake street, Aurora, Ill. Besides conducting a garage business Arr. Hill will conduct a regular blacksmith's shop and a second hand carriage business.

Contracts have been let for a \$20,000 garage building at Center and Morewood avenues, Pittsburg, Pa., for A. E. Pitcairn. The lot has a frontage of 46 feet, is 100 feet deep and 81 feet wide in the rest.

wide in the rear.

J. H. Flemming, Media, Pa., will open a garage in the old Market building at Front and Orange streets. Mr. Flemming formerly conducted a garage in the same building, but closed it to start a similar business in Baltimore.

Chas. E. Myers, Washington agent for Elmore cars, has purchased a half interest in the Vermont Garage, 1122 Vermont court, Washington, D. C., The Elmore cars will in the future be handled in Washington from this address.

Work has been begun on the new Totten Garage on Third avenue near Seventeenth street. Davenport, Ia. The building will be 40x100 feet, and two stories high. The garage will be fully equipped and a line of cars will be handled.

The Auburn Motor Company, of San Francisco, have moved into new quarters at 407 Golden Gate avenue. A permanent structure will be built for Walter C. Morris, agent for the Autocar, on the site of the building formerly occupied by the Auburn Company.

The Imperial Garage has been removed from 52-54 West Sixty-seventh street to 208-212 West Seventy-sixth street. New York city, where it will be opened for business September 1. The firm will hereafter be known as the Imperial Motor Vehicle Co. S. C. Stinzing is manager.

The United Motor Company, Wichita, Kans., has moved to 114 North Emporium street, into a new building containing a 52x100 feet showroom addition to office space. The company handles

the Auburn, Interstate and Mitchell cars. Morris L. Arnold is manager of the concern.

The building at the corner of Massachusetts avenue and Newbury street, Boston, Mass., has been sold to the Maxwell-Briscoe Motor Company, and will be fitted up as a permanent branch for that company. The site extends 112 feet on Massachusetts avenue and 125 feet on Newbury street, and is improved with a four story structure erected in 1892. The price paid is understood to have been in excess of \$300.000.

Charles S. Henshaw has been engaged by the E. R. Thomas Motor Company, of Buffalo, N. Y., to open and manage a branch of the company in Boston, Mass. The new arrangement took effect on August 1. For the present headquarters will be at 288 Columbus avenue, from where Mr. Henshaw formerly sold Thomas cars for a number of years, but arrangements will be made shortly for better headquarters. A new company will be organized.

The Pence Automobile Co., Minneapolis, Minn., are this week moving into their new building on Hennepin avenue and Eighth street. It is an eight story and basement structure, and the floor space is divided as follows: Basement and seventh floor, storage: first floor, offices and salesroom; second floor, garage; third floor, taxicabs; fourth floor, paint shop; fifth floor, stockroom for parts and accessories; sixth floor, top manufacturing and metal department; eighth floor, repair shop. The company handles the General Motors line.

### Trade Personals.

S. A. Dutton, formerly with the Racine Mfg. Co., has been appointed advertising manager of the Overland Automobile Co., Toledo.

Hazlitt L. Pelton, formerly San Francisco manager of the Tourist car, is now sales manager for the Reliance Automobile Co., agent in San Francisco for the Knox car.

Evan Shelby, of West Lafayette, Ind., has sold his garage in Crawfordsville, and has become territorial manager for the Buick Motor Co. Mr. Shelby handled the Buick for a number of years.

George B. Levy has resigned as president and general manager of the Standard Automobile Supply Co., Chicago, Ill., and has been succeeded by L. I. Brignan, who is the principal stockholder in the concern.

John G. Dale, formerly connected with the sale of the Fiat, Rochet-Schneider and other imported cars in this country, has been appointed the executive sales agent for the Simplex Automobile Co., New York.

H. F. Edmiston has assumed the position of manager of the retail department for the Gaeth Automobile Co., Cleveland, Ohio, and will have an office and salesroom at 152 Euclid avenue. Mr. Edmiston formerly conducted a business college in Cleveland.

F. R. Heym, for the last five years superintendent of the Burroughs Adding Machine Co., and who has served in various official capacities for fourteen years with the Brown & Sharpe Manufacturing Co., and for seven years with the American Screw Co., both at Providence, R. I., has joined the firm of Schweppe & Wilt, parts makers. Detroit, as factory manager.

# New Incorporations.

Vulcan Motor Co., Pittsburg, Pa.—Capital, \$5,000.

Gary Motor Car Co., Muskegon, Mich.—Capital stock. \$200,000.

Excelsior Automobile Supply Co., Chicago, Ill.— Capital stock increased from \$10,000 to \$50,000. Standard Automobile Supply Co., Chicago, Ill.—

Capital stock increased from \$30,000 to \$50,000.
Crow Motor Co., Elkhart, Ind.—Capital stock.

\$50,000. Incorporators, Frank A. Howe, Edward C. Crow and Martin E. Crow.

The Duquesne Auto Co., Pittsburg, Pa.—Incorporated in Delaware. Capital stock, \$3,000. Incorporators, Geo. A. Holliday, F. B. Minnick and Kirk Q. Bigan.

The Parry Auto Co., Indianapolis, Ind.—Capital stock, \$1,000,000. Incorporators, David M.

Parry, M. O. Parry, Addison J. Parry, Warren Oakes and W. C. Teasdale.

Robinson Auto and Supply Co., St. Joseph, Mo.—Capital stock, \$10,000. Incorporators, E. A. King, R. E. Calkins, W. M. Smith, Leo Muchenberger, W. H. Robinson and others.

The Badger Automobile Co., Columbus, Ohio.— Capital, \$50,000. Incorporators, A. M. Bellack, president; C. Kurth, vice president; Geo. Holtz, secretary, and J. R. Wheeler, treasurer.

Brookston Automobile Co., Brookston, Ind.— Capital stock, \$7,000. Incorporators, Milton Gay, J. H. Kneale, W. C. Holstead, John J. Nagle, Ira Bordner, C. J. Murphy, R. C. Alkire.

The Ogden-Farwell Garage Co., Milwaukee, Wis.—Capital stock, \$10,000. Incorporators, George F. Gerlach, J. M. Dorsey and A. C. Runkle. The company has been in business as a partnership for about a year.

partnership for about a year.

The Superior Motor and Machine Works, Duluth, Minn.—Capital stock, \$15,000. To manufacture and deal in automobiles, launches, steam and gasoline engines. Incorporators, Solon L. Perrin, Dr. H. J. O'Brien and H. C. Lavery.

#### New Agencies.

Atlanta, Ga.—R. C. Howard, Mitchell. Duluth, Minn.—A. J. Gerald, Stearns. Washington, D. C.—John J. Fister, Mora.

San Francisco, Cal.—Reliance Automobile Co., Knox.

Oconomowoc, Wis.—The Leaf Automobile Co., Kissel Kar.

San Francisco, Cal.—Howard Automobile Co., Oldsmobile.

Springfield, Mass.—Corcross Cameron Co., Chalmers-Detroit.

Yonkers, N. Y.—Rose & Hibbard, Hudson and Chalmers-Detroit.

Kansas City, Mo.—H. H. Embry, 1526 Grand avenue, Pierce-Arrow.

Chicago, Ill.—B. C. Hamilton & Co., 1218 Michigan avenue, Chadwick Six.

Kansas City, Mo.—Louis A. Robertson, 1108 East Fifteenth street, Empire.

Youngstown, Ohio.—The Elton Auto and Repair Co., Front street, Stearns, Cadillac and Detroit electric.

### Patents Issued July 13, 1909.

NUMBER 6

# Practical Self Starting on the Spark.

By A. C. WOODBURY.

It is my belief that any four cylinder engine which is furnished with a battery and jump spark ignition with magnetic vibrator can be made to start on the spark. I have run several marine engines of a certain make on blocks in the shop. They were fitted with a carburetor which did not give a very good starting mixture; indeed we usually found the easiest way to start was for one to nearly cover the carburetor inlet with his hand while another cranked. Nevertheless, these engines started very regularly on the spark, even after the cylinders had become cold. They started on the witch repeatedly after standing over an hour, after having the pet cocks opened to release any compression which might remain, and after opening the pet cocks when the cylinders had become quite cold. They also sometimes "sparked up" after standing over night. With the spark retarded so that the points were always in contact in the timer when the engine stopped, I could stand at the switch and start and stop the engine every time, just as you start and stop the electric fan on your desk, by merely closing and opening the switch.

I believe there are not a few drivers and owners of four cylinder cars who do not clearly understand what occurs when an engine starts on the spark, or indeed why it will start so at all. This is either through lack of thought on the matter or because they have not a full understanding of what is taking place in each cylinder at every point in the cycle of operations of the engine. The following four paragraphs are meant for such.

### HOW AN ENGINE STOPS.

Whenever a four cylinder, four cycle engine in normal working order is coming to rest after the ignition is interrupted, it turns over a few times till the energy stored in the flywheel is so far dissipated that it will not carry through the compression stroke and over the dead centre The charge which was then being compressed now forces the piston back, turning the flywheel backward. In another cylinder a charge (unburned, because the ignition had been stopped) was being expanded. Now, as the flywheel starts backward this charge is compressed again. The flywheel is stopped again by this charge before the crank has passed dead centre, and after a few oscillations comes to rest with the cranks practically horizontal. This is because one valve in each of the other two cylinders is open (if the inlet valves are mechanically operated) and there are substantially equal charges confined in the two cylinders whose valves are closed. Therefore, in order to have the pressures equal on the pistons (the condition of rest), these equal charges must occupy equal volumes, thus bringing the pistons to the same level.

The line sketch, Fig. 1, may help to make this perfectly clear. It represents an engine which fires in the more common order of 1-3-4-2 and rotates in the customary direction, i. e., the top of the flywheel, shown at the rear, turns toward the left of the car. The exhaust valves are marked E, and inlets I. The crank shaft, pistons and valves are shown in one of the four positions in which they might stop. The first and fourth crank throws are toward the right—going up if the engine were rotating forward—while the second and third are toward the left—going down. The exhaust

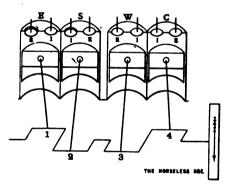

Fig. 1.

valve of the first cylinder is open so the first piston is on its exhaust stroke, and the fourth must be on its compression stroke. The third piston would then be on its expansion or working stroke and the second on its suction stroke with its inlet valve open. Letters over the cylinders show which stroke the pistons are on. The table below also shows in the first line the positions as in the figure, and in successive lines the positions after successive forward half turns of the crank shaft. E denotes

Cylinders.				Valves C	Position	
ſ	2	3	4	Exhaust.	Inlet.	of Crank.
E	S	W	С	I	2	As shown
S	C	E	W	3	1	Opposite
С	W	S	E	4	3	As shown
W	E	C	S	2	4	Opposite

exhaust; S, suction; W, working, and C, compression.

If the engine fired in the other possible order, 1-2-4-3, the positions of cylinders 2 and 3 would be simply reversed.

# AUTOMATIC INLET VALVES.

In the case of automatic inlet valves, the inlet valve which was open just before the flywheel stopped and reversed its direction for the first time will then close and remain closed, thus confining a partial charge above the piston which moves with the one which was expanding its charge. This tends to make the two pistons which are stopped on the down stroke slightly lower than the others, but not enough to seriously affect the starting on the spark. The difference it does make will be noted later.

#### HOW THE SPARK STARTS IT.

Fig. 2 shows the timer in about the position it would normally be to correspond with Fig. 1. The inside arrow shows which way the shaft and wiper arm rotate, and the arrow on the operating rod shows the direction to move it to advance the spark. With the rod as shown the spark will begin about on dead centre, but with the engine at rest we see that there is no contact in the timer, therefore no spark in any cylinder. However, if there is room enough for the required motion of the spark lever on its quadrant we can produce a spark in the fourth cylinder by advancing the spark. or in the third by retarding. In any case advancing will cause the spark to come in the compression stroke and retarding will bring it in the expansion or working stroke. It is sometimes possible to start an engine by advancing the spark till the engine kicks backward, then quickly retarding it to catch another piston, after which it must make a whole revolution forward before another cylinder will fire. This method is uncer tain and involves an explosion of full force against a piston and flywheel going backward, so I do not think it worth serious consideration.

In order to start the engine forward from the position shown we should produce a spark in the third cylinder—i. e., retard the spark. We should then get an explosion of sufficient force to start the engine forward half a revolution. This half revolution of the engine will turn the wiper arm of the timer 90 degrees in the direction of the arrow. By this time it would make contact at 4 in spite of being retarded a little from the position shown, and would cause a spark in the fourth cylinder which is now on its working stroke, as shown by the table. Another half turn of the engine with the corresponding quarter turn of the

wiper arm will bring a spark in the second cylinder, which our table shows will then be on its working stroke. Thus the engine continues to run, although it will give very little power till the spark is advanced.

WHY SOME ENGINES FAIL TO START ON THE SPARK.

If any four cylinder engine will not start from the switch it must be either because the ignition system is incapable of producing a spark in the cylinder whose piston is stopped on its working stroke, or because that cylinder, or one of those following, does not contain a charge of quality to be ignited or of quantity to throw the engine over the dead centre.

#### THE SPARK OFTEN AT FAULT.

Some cars are arranged with rather limited motion of the timer lever. This is not without reason, as it may be made to prevent unskilled drivers from running with the spark so much retarded as they otherwise might, or from advancing it too far. In other cars also the adjustment is such that with the lever in the position of extreme "retard" the spark will come about on dead centre—the best position for

cranking. With such an adjustment starting on the spark is impossible, as the timer cannot be thrown around far enough to make the contact necessary to produce a spark above the piston which has stopped on its working stroke—No. 3 in the figures. Any advantage gained by the above adjust-

ment must therefore be sacrificed for starting on the spark.

The simple remedy is to lengthen or shorten some rod in the connections so the spark can be retarded enough to make the vibrator buzz with the engine in the position in which it naturally stops. An adjustment is usually provided which may be sufficient.

In some cases it will be found that when the spark is retarded the timer arm and rod are as shown by the dotted lines in Fig. 2—too nearly in a straight line for safety. In one such case I had the rod A lengthened two or three inches so as to bring the timer arm around about 90 degrees, as shown by the full lines, then each wire on the timer was moved to the next post in the direction of the arrow.

In case the motion of the timer lever is not sufficient to give enough advance when the timer is adjusted to "spark up" the simplest remedy will usually be to make the timer arm shorter, as by drilling a hole at B. or to make the lever at C longer. The arrangement may be quite different from this, but almost always a lever can be found which can be made longer or shorter, as required, to make the motion of the "mer greater for the same action of the

Of course, as ordinarily constructed, an engine provided with magneto ignition only, with contact spark, or with non-vibrator coils, cannot start on the spark; but that all can be so constructed as to gain this end is shown by the following: Magnetos have been made to produce a spark without turning the engine over; the Matheson engine (contact spark) is provided with means for snapping the spark plug of the proper cylinder for self starting, and the Atwater Kent system provides a starting spark from a non-vibrator coil. WHEN THE VIBRATOR WILL BUZZ WITHOUT A RESULTING EXPLOSION.

The trouble in this case is not with the spark but the charge. The nature of the charge and conditions affecting it have been quite fully discussed in The Horseless Age by J. V. S. Bickford ("Self Starting Devices," December 2, 1908) and "The Trouble Man" ("Expedients by Which Starting on the Spark Can Be Made More Certain," May 5, 1909). The interested reader is referred to these articles. I will repeat only enough to say that the fault is almost always too little gasoline in the

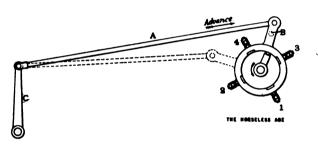

Fig. 2.

mixture, and some carburetors cannot be adjusted to give a mixture rich enough for easy starting, on the spark or otherwise, without giving too rich a mixture for economy and best results in running. In this case the remedy is to provide convenient means for flooding the carburetor or partially closing the air inlet while the motor is stopping.

The impression seems to be very general that an exceptionally gas tight cylinder is a condition necessary for self starting. That this is not the case can be proven on almost any motor which starts readily on the spark if it is provided with interconnected relief cocks. Open the cocks for a moment to let all the pressure out of the cylinders, and it will start almost as surely as when they are left closed. If an engine which starts on the spark immediately after stopping fails to do so after standing it is not because the pressure has fallen through leakage, at least to the extent that many engines start in spite of that. The trouble is that the gasoline has condensed and perhaps gathered on the cylinder walls so that the mixture is left too weak to be ignited without compression, or to provide sufficient force to start the engine if ignited. To extend the possible time of rest before self starting make the mixture a little richer in stopping as suggested above. I believe that most engines can thus be made to start on the spark almost every time after a stop of ten or fifteen minutes, generally after an hour, and sometimes after standing for a day or longer. In the winter or late fall there is not so much chance of starting after the water in the jackets has lost its heat.

WHEN THE MOTOR "KICKS" BUT DOES NOT CONTINUE TO TURN.

If any explosion occurs the motor is almost sure to go over the centre and make about half a revolution. Then it is "up to" the cylinder which stopped on its compression stroke. This was the last one to draw in a full charge as the engine stopped. and may have a poorer charge than the one ahead, as the speed of the engine was then slower. In an engine fitted with automatic inlet valves this piston is likely to stop higher than the middle of the stroke. as explained above under "Automatic Inlet Valves," so if the charge has had time to leak out there is only a small amount left. The spark will also have to be retarded more to make the first buzz of the vibrator, because the engine stops in a slightly different position. However, the engine is already turning when this cylinder fires, under some compression, so it will usually do its duty.

Aside from enriching the mixture in stopping this condition can be relieved by the following expedient: Place the spark lever in the position on the quadrant known to bring the spark on dead centre. (This point should always be known and marked.) Close the ignition switch and place one hand on the quadrant and against the spark lever, so as to prevent advancing the spark beyond that point. Now with a quick motion retard the spark to the limit, or at least far enough to cause the vibrator to buzz, and bring the lever back against your hand instantly. This causes the spark as required in the cylinder which stopped on its working stroke, and yet brings the spark in the next cylinder where its charge is most compressed, most likely to be ignited, and able to do the most work of which it is capable instead of after it has partly expanded again and has only part of a stroke left in which to work.

If an engine stops after two cylinders have fired and it has turned a full revolution it would not start with the crank without priming or its equivalent. But the cylinder which would fire third was left with a partial charge and its inlet valve open, so it has to rely for its charge, at least partly, upon what it draws in as the engine starts at about cranking speed. So it may be that an engine which kicks over and then stops can be kept going by priming the carburctor before starting or by partly closing the air inlet for a moment as the engine starts.

### IN CONCLUSION.

It is well to remember, as hinted by "The Trouble Man," that in adjusting for a rich enough mixture at extremely low

speeds there is danger of getting an unnecessarily rich mixture for ordinary speeds. This will cause sooting and a slow burning mixture with loss of power, overheating and burning of exhaust valves. It is better to make the mixture right for best running and provide means for priming or otherwise temporarily enriching the mixture.

Self starting is very convenient, especially for one who makes frequent stops, and self starting on the spark can be made quite reliable, at least for a short talk at the roadside or a stop for a frightened horse. I hope this may help some users to save labor at the crank and enjoy one more of the luxuries of motoring.

# Energy Consumption of Commercial Vehicles.

Paper read by Alex. Churchward before the Society of Automobile Engineers at Chicago.

When studying the performance of the motor vehicle, one of the most important items is the energy required per ton mile. We can rely upon the engine to give a certain horse power output at a predetermined speed. Therefore, knowing the maximum horse power output of the engine, we can readily determine what service the vehicle is capable of performing.

is capable of performing.

The horse power required by a vehicle, however, is influenced by a number of factors, the principal ones being:

# I.-TIRES.

Ordinarily the standard vehicles are equipped with either pneumatic or solid tires, pneumatic on the lighter vehicles, such as runabouts, coupés and broughams. Solid tires on some runabouts and cabs, and nearly always on commercial vehicles.

The tractive effort of pneumatic tires on hard level asphalt varies from 15 pounds per ton for special tires designed for electric runabouts up to 35 pounds per ton for the standard type used on gasoline touring

The tractive effort of pneumatic tires is also greatly affected by the air pressure, increasing rapidly as the air pressure is reduced.

The tractive effort of solid tires on hard level asphalt varies from 18 pounds to 26 pounds per ton, depending upon:

(1) The diameter of driving wheels.

(2) Revolutions per minute.

(3) Load in pounds, per square inch or pounds per inch width.

(4) Composition of the compound used.

(5) Method of attaching tire to wheel

# 2.—CONTROLLING APPARATUS.

The efficiency depends a great deal upon the type of drive used, such, for instance, as:

- (1) The sliding gear with direct drive on the high through a bevel on live rear axle.
  - (2) Sliding gear with direct drive on

high through countershaft and chains to dead rear axle.

- (3) Sliding gear, not direct on high, and through countershaft and chains to dead rear axle.
- (4) Planetary with direct on high by means of bevel or chain to live rear axle.
- (5) Planetary countershaft through chains to dead rear axle.
- (6) Friction gear to live rear axle through bevel or chains.
- (7) Friction gear to dead rear axle through chains.
- (8) Worm drive direct on high to live rear axle.

Some form of independent clutch being used on the 1, 2, 3 and 8.

#### 3 .- TRANSMISSION LOSSES.

These include gearing or chain losses, and all bearing losses throughout the vehicle. Most vehicles today are built with anti-friction bearings throughout.

Ball bearings should always be used in the countershaft; ball or roller bearings in the wheels. Personally, I prefer ball bearings throughout, and my experience has shown that ball bearings in the wheels are perfectly reliable when properly selected and correctly installed.

From countershaft to wheels the roller chain has proven itself satisfactory, but care must be taken in the selection of the make of chain, also the right pitch and number of teeth in the sprockets.

4.-ALIGNMENT OF AXLES AND DRIVING

### MECHANISM.

Unless the alignment is perfect under all conditions of maximum stress the energy consumption will be high. An axle sprung beyond the elastic limit by overloading may increase the energy consumption .10 per cent. to 15 per cent.

A vehicle that coasts freely may require too much power when the driving stresses are applied.

Therefore, all parts must be in perfect alignment under all conditions to be met with in service.

# 5.—CORRECT GEAR RATIO.

Unless the gear ratio is correct for the average service the vehicle is called on to perform the motor will either run at too high an average speed or the change gears will have to be used very frequently, which will tend to increase the maintenance of the vehicle when placed in the hands of a careless driver.

### 6.-WHEEL DIAMETER.

Small wheels will increase the energy consumption materially on the average roadbed, because the smaller the wheel diameter the greater the vehicle vibration when going over an obstacle of a given

### 7.—SPRINGS.

The springs of a vehicle must be correctly proportioned and of suitable material, otherwise there will be considerable movement of the vehicle body when going over uneven roads; this, of course, means energy consumed which cannot be restored.

#### 8.—ROAD RESISTANCE.

The tractive effort of a vehicle will vary with the road surface as per table, taking the tractive effort of a vehicle on hard level asphalt as unity:

(1)	Level asphalt (hard)	1.00
(2)	Wood pavement	1.15
	Level macadam	5 to 3
(4)	Plank road	.9
	Cobble stones	1.75
(5)	Good dirt road 1.1	to to 2
(6)	Ordinary country road (dirt)	.2
(7)	Sand	.20

Q.-GRADES.

The tractive effort due to grades must be added to the tractive effort for a given road surface.

Example: 5 per cent. grade on hard level asphalt. Hard level asphalt 25 pounds per ton. 5 per cent. grade = 100 pounds per ton, due to grade alone. 100+25 = total tractive effort = 125 pounds per ton.

# IO .- WIND RESISTANCE.

Below 12 miles per hour the additional tractive effort necessary to overcome the wind resistance on heavy vehicles is comparatively small.

But on the light, high speed vehicles, when running at speeds above 12 miles per hour, the wind resistance becomes quite a large factor.

#### II .- ECONOMIC SPEED.

Taking everything into consideration, that is to say, life of engine, transmission, tires and maintenance of vehicle as a whole, experience shows that the following table is approximately correct:

ross Weight.	Type	Speed in
Pounds.	of Tires.	M. P. M.
1,500	Pneumatic.	20
2,000	Pneumatic.	20
3,000	Pneumatic.	18
4,000	Pneumatic.	16
2,000	Solid.	16
3,000	Solid.	15
4,000	Solid.	13
5,000	Solid.	11.
7,000	Solid.	9
10,000	Solid.	8
15,000	Solid.	7
20,000	Solid.	6
	12.—STOPS.	

The number of stops per mile will have a considerable influence on the energy consumption of a given vehicle.

# 13.-ACCELERATION.

It should never be too rapid; if it is, there is danger of damaging the engine or snapping a chain or gear.

It can be seen from the preceding items that there are a great many factors which influence the energy consumption, and, therefore, the performance of a commercial vehicle.

J. D. Siddeley, who for a number of years was general manager of the Wolseley Tool and Motor Car Company, Ltd., of Birmingham, England, has been appointed joint managing director of the Deasy Motor Car Manufacturing Company, Ltd.

# The Automobile Situation in Washington, D. C.

By H. H. BROWN.

Washington is an ideal city for the demonstration of the automobile for both pleasure and business purposes. Nowhere in the city is traffic ever congested. The streets and avenues are, without exception, more than ample for the travel on them, and, while the city cannot be said to be square shaped, yet, unlike New York, it spreads out in all directions, and through traffic is not confined to two or three main thoroughfares. Then, again, while numbered streets run north and south and lettered streets east and west, avenues running diagonally intersect the others every four or five blocks, so it is possible to take almost a straight line from point to point instead of following the usual two sides of a rectangle. The grades are easy and the streets are kept in fine condition at all times. This is rendered especially easy by the fact that Washington is almost entirely a residential city, and there is little or no regular heavy trucking to put the streets in bad condition. Again, owing to the somewhat southerly location of the city, traffic is very little impeded by snow or other weather conditions. ELECTRICS POPULAR

Perhaps the most striking feature of the automobile situation in Washington is the extensive use of electric vehicles, especially runabouts. It is said that there are more

Owing to the extremely wide streets there are no traffic regulations limiting the time during which a machine can stand in one place, nor are there any as to the side of the street on which the car shall stand. It is therefore customary not only to leave a machine unattended during shopping and business calls, but also during attendance at the theatre. In some places where many automobiles are left unattended for some time it has been the custom to back them up to the curb instead of running them alongside, as is generally done. About the only automobile traffic regulation which is strictly enforced is that which forbids the dropping of oil. Speed regulations are enforced by bicycle police, who have their wheels equipped with speedometers, but as most drivers show consideration for the users of the highway no considerate driver need fear arrest for what may be called technical violations of the speed law.

On arriving in the city of Washington one is almost sure to run across electric automobiles before leaving the train shed, as two electrically driven baggage trucks are in use in the terminal station. These were put in operation when the terminal station was opened for traffic, and from the engineering standpoint have been a success. As to just how successful they are from the

with this trouble the Senate office building was erected on B street, right across from the Capitol. To facilitate communications between the two buildings a subway was built between them. This subway is about 25 feet wide, with a raised sidewalk to one side, railed off from the roadway. The flooring of the subway is of cement, as smooth as the proverbial billiard table, but with a grade of about 2 per cent down toward the office buildings. The length is about one-eighth mile, and the line of the subway is slightly curved. It is heated by steam in winter and lighted brilliantly at all times with electric lights.

#### DESCRIPTION OF CARS.

The two machines used are electrics They are equipped with 5 horse power motors and batteries of twenty-four cells each. Their design is somewhat peculiar. as they are built especially for the service. There are two drivers' seats, one facing one way, and the other the other. The passenger seats are arranged longitudinally, vis-à-vis, there being one pair of seats for six at one end and another for four at the other, there being steps at both ends. The drivers' seats are located "amidships," the control being on the left. Two complete sets of controllers are in use, one for each seat. This, of course, makes the cars double enders, so that they can be driven up to either end of the subway and then returned to the other end without turning round

A MOTORCYCLE DELIVERY VAN WHICH MAKES FORTY MILES PER DAY ON A MILK ROUTE.

BRUSH DELIVERY SIMILAR TO THAT USED IN MAIL COLLECTION CONTRACT.

electrics used in the city of Washington than in any other city of its size in the country. Most of the electrics used are kept in public garages, and the price charged not only includes washing and polishing but also charging and calling for and delivering the machine to the owner at least once a day. Considerable business is also done by the garages in charging during the day electric machines which are kept at owners' private garages or stables during the night. This while the owners are attending to business in the city.

economic point of view would be hard to

CAPITOL SUBWAY CARS.

Another peculiar use of the automobile is as a sort of horizontal elevator in the sub-way which connects the Senate chamber with the Senate office building. There are a large number of Senate legislative committees which report on and revise bills brought up for action by both houses. Formerly these offices were scattered round in many buildings, and much valuable time was lost in going to and fro. To do away

At the Capitol end there is a platform which is level with the vehicle platform at the office building side. The steps are used, however. The normal seating capacity of the machines is ten, but during rush hours, when the Senate is opening or closing, as many as eighteen are carried. The machines are operated simultaneously, one being at one end and the other at the other. When one is ready to start the driver rings his bell, and they both start up simultaneously, or nearly so. Thus most of the time there is a machine ready to start

BELMONT GARAGE, ONE OF THE LARGEST IN WASHINGTON.

at either end. Two sets of batteries are kept in reserve; they are charged in the dynamo room of the office building, and in case of a battery running low it is a matter of seconds rather than minutes to change batteries. However, this hardly ever needs to be done during running hours, since the machines are capable of making about 40 miles on a charge, which is equal to upward of 300 trips

Property suitable for garages rents somewhat lower in Washington than in most other cities, and the cost of labor is also lower. The consequence is that the "elevator" garage is conspicuous by its absence. In most cases the garages are of one story only.

However, there are some of two stories, the upper story being used for offices, locker rooms, dead storage and repair shop. An example of this type is the Belmont Garage, which is built especially for the purpose, the walls being of brick and the flooring of reinforced concrete.

# WEEKING CAR EQUIPMENT.

A rather interesting piece of apparatus used in this garage is a wrecking car which was remodeled from a well known double opposed cylinder model of 1903. The tonpeau of the machine was removed and a large tool box was put in its place. This box measures about 4x21/2x2 and while in the garage is kept locked, employees being forbidden to borrow tools from this car under any pretext. The tool box contains all tools ordinarily used in the shop. besides several special tools and appliances. Among these are a couple of bogie trucks. These are equipped with 20 inch wheels and have a curved iron piece secured to a block on the axle by means of which they can be readily lashed to the springs of a disabled vehicle. Another special piece of apparatus is a spare wheel which is fitted with bushing so that it may be placed on any axle from which a disabled wheel has been removed.

Another feature of the car is a power winch. This is placed on the platform formerly occupied by the tonneau. To use the same the driving chain is disconnected from the rear axle and a special driving chain is connected from the countershaft sprocket to that of the winch.

For use in connection with this device, a block and fall are kept in the tool box. A minor feature of the equipment of this car is the use of portable stands for the searchlights and plenty of tubing by means of which they may be connected to the generator and be placed advantageously for furnishing light for a night repair job.

# MOTORCYCLE CARRIERS.

The use of the motor vehicle for commercial and public services purposes has in general progressed as well as in other cities of the same size. There is one line of taxicabs operated in the city, but these are not so much in evidence, since local conditions do not favor their use as much as in more cosmopolitan cities, such as New York. There are quite a number of sight-seeing cars in use and also delivery wagons of the usual types. Perhaps the most interesting phase of the commercial side of the automobile situation in Washington, however, is the use of the lighter forms

of vehicles for mail collection and light parcel delivery.

Several light motorcycle delivery vans have been in use for some time in various lines of business, some having been in use for a period of as long as two years. They have been used for the collection of mails by the Post Office, for collection and delivery of books by the Public Library and by florists, caterers and book stores-in some cases for special emergency delivery and again for regular work. Most of these machines average about 40 miles per day and are capable of something like 60 miles on one gallon of gasoline. Perhaps the best idea of the economical operation of these machines will be obtained from the fact that the agent of one of these makes stands ready to furnish gasoline and all supplies including garaging and tires, in fact everything except repairs necessitated by an accident, on a yearly contract at \$18 per month, the only condition being that one man only be employed to operate the machine, so that it will not constantly be in the hands of inexperienced men. The fact that none of the purchasers of the machines have taken advantage of this offer shows that these figures have been found by experience to be more than ample.

This same agent recently made a proposition, in fact a bid, to the Post Office to furnish a machine on a yearly contract at \$360 per year. This included rent of machine and all supplies, on a route of 40 miles per day. He also agreed, in case they made a contract for four machines, to furnish or keep in stock an extra machine to be used when any of the other machines was laid up for repairs or for use during the rush seasons.

# MOTOR MAIL COLLECTION.

Perhaps one of the most interesting phases of motor vehicle service in Washington is in the collection of mail from mail boxes, as this service is also very hard on all parts of a car, owing to the numerous stops made in a given time. The Brush-Nichols Company have a year's contract

AUTOMOBILE COLLEGE OF WASHINGTON.

with the Post Office Department to furnish three machines for sixteen hours per day with driver to do such work as may be required of them. At present these machines are in use at three stations for mail collections. They make an average mileage of 102 per day and collect on an average over 100 boxes per trip. They each average four trips per day. A collector accompanies the driver and rides on a wide step in the rear of the machine. Between boxes he empties his bag into larger bags inside the body. It is claimed by the post office authorities that one of these machines does the work of twelve carriers either on foot or on a wheel. The machines are equipped with solid tires.

It has been found that the average cost per machine under these conditions of service is about \$200 for repairs and replacements, including cost of tires. This service is very severe on a car. It has been estimated that the average business wagon makes an average of only about seventy-five stops per day as against about 500 in mail collecting work. Then again, in many cases the machines are overloaded. The load capacity guaranteed by the makers is 500 pounds.

The contract price to the Post Office for the use of the three machines with drivers is \$14,600 per year. At first this may seem a trifle high, but it should be remembered that there is a penalty for delays in collections and that a fourth wagon is kept in reserve for use when one is undergoing repairs. In fact, there are two extra machines available for special rush season work.

There are also quite a number of these machines in use for various commercial delivery purposes, in the service of florists and butchers, and these are giving satisfaction. Considering that they cost about the same as a good horse and team the work which they do would seem to be very creditable.

### AUTO COLLEGE.

As far as could be ascertained there is only one automobile school in Washington. This is known as the Washington Automobile College. The proprietors of this school deal in second hand automobiles. This gives the students a chance to look over a variety of machines. Their lecture or class room is equipped with a stripped chassis and there are also a number of coils, carburetors and various parts which are used to illustrate the points brought up during the theoretical instruction.

# New Photographic Device for Determining Vehicle Speeds.

By WALTER H. HILDERRAND.

No objection to the perfection of the motor driven vehicle stands out as prominently as the dread felt by the public toward over-speeding automobiles. Stop watches, with tapes at quarter mile intervals, have been employed in upholding speed

ment have been imposed for reckless driving. But the method of conviction, based as it is in many instances upon the word or judgment of a single deputy, has proven universally unsatisfactory.

An instrument which eliminates this difficulty has been found by Drs. Herbert T. Kalmus and Daniel F. Comstock of the physics department of the Massachusetts

SPECIMEN PHOTO TAKEN BY AUTO SPEED RECORDER.

Institute of Technology, in their researches toward the establishment of a mechanical means for recording the velocity of a moving object. The photo speed recorder finds its most novel application in the conviction of auto speeders, and several fines have already been imposed in Boston courts, based upon the evidence rendered by the photographs.

Two cameras enclosed in a single cover take instantaneous exposures of the automobile, one approximately a second after the first. During the interval, the machine has traversed a certain distance which may be readily calculated from the two photographs, following an established rule relating to lenses.

The relation of the size of an object to its image is known to be exactly equal to the relation of the distance of the object from the lens to the distance of the image from the lens. In the computations, the size of the object is taken as the wheel tread of the automobile. The size of its image is readily measured from the photograph by means of a steel scale graduated to hundreths of an inch, and the distance of the image from the lens, which corresponds to that of the plate holder from the aperture, is accurately determined for each instrument. With this data it is a simple matter to find the distance of the object from the camera at each exposure; the difference in the two results gives the distance through which it has moved.

To determine the exact time of the interval between exposures, a chronometer is placed inside the instrument directly in front of the plate holder, an image of the moving hand appearing against a fixed dial on each photograph. One half revolution of the pointer indicated exactly one second, and the time interval may be read to a thirtieth of a second by noting the difference in dial setting. Having found the distance and the time, the velocity is established accurately by this method to within a fraction of a mile per hour.

Purely mechanical in operation, the camera need only be pointed at a moving object and a lever pressed at its side. Automobilists and officials alike should welcome an innovation which eliminates all personal element from an arrest for reckless driving shows the number and surroundings of the speeding machine, and in many cases even records its occupants.

# Registrations in California.

During June of this year 885 motor cars were registered at Sacramento in the office of the Secretary of State of California. In May there were 938 registrations, and in April, the record month, there were 953. The number of registrations is, however, higher than in June of any year since the law went into effect. In June, 1905, there were 498 registrations; in June, 1906, 313; in June, 1907, 561, and in June, 1908, 519. During the first six months of 1909 there were 4,517 registrations, as against 3,010 for the first half of 1908. The total registration for 1908 was 5,558.

During June, 1909, there were 231 transfers of motor vehicles, the number in May having been 180. During the first six months of the year there were 732 transfers, while for the same period last year there were 409. The total number of transfers for 1909 was 891. One hundred and seventy-three licenses were granted to chauffeurs during the month of June.

# The Pros and Cons of Offset Cylinders.

The practice of offsetting the cylinders relative to the crank shaft is spreading in this country, and for good reasons. We believe that it is generally understood that the advantage of offsetting is that it reduces the side thrust on the cylinder wall during the power stroke, thus saving power and reducing the wear of the cylinder bore. It is true that offsetting increases the side thrust on the cylinder wall during the compression stroke in the same proportion, but as the piston head pressure during the compression stroke averages only about onefourth as high as during the power stroke, the gain far outweighs the loss. There can be no doubt that the offset cylinder motor possesses a higher mechanical efficiency than the "straight line" motor, other things being equal. The difference, of course, can amount to only a few per cent., and could herdly be expected to be clearly discernible in indicator diagrams or the results of brake tests

We have never heard a plausible argument against the practice of offsetting, except that it slightly disturbs the balance of the moving parts. Considerable importance

has been attached by some writers to the fact that a certain English firm has discarded the principle. It may be said, however, that this firm, whose product is distinguished by high grade workmanship, has always been regarded as several years behind the leaders in engine design, and so this particular move on its part is not likely to make any great impression among engine designers. Moreover this firm now uses a special type of engine, and even though offsetting were proved to be undesirable for that type, it by no means follows that it is also of no value for engines of the conventional type.

# A Revival of the Combination Power System.

The combination system of automobile propulsion, by means of electric motors receiving current from a gasoline engine driven generator carried on the car, is recently being taken up again in connection with commercial vehicles. The system found much favor with inventors in the early years of the industry, and many different combinations were worked out, some including also a storage battery. The system never gained a foothold, but it is to presumed that many of the failures were due to the crudeness of the various elements, notably the gasoline engine, at the time.

Recently one of the big express companies operating in New York city has transformed a number of its electric trucks by providing them with gasoline engine-generator sets to take the place of the storage battery, and we notice that several Western firms are preparing to place trucks with such a power system on the market. The object is, of course, to eliminate the weakest features of both the gasoline truck and the electric truck, and in a way combine their advantages. The most delicate part of the gasoline truck, especially for operation in crowded thoroughfares, is undoubtedly the change gear. The constant stopping and starting is very hard on the gears, and they wear out rapidly. The sliding pinion type of gear requires more or less skillful handling, and necessitates the employment of more expensive drivers than would otherwise be necessary, and the other types of change gears also have serious shortcomings when applied to this work. The weakest part of the electric truck always has been the storage battery. It is very heavy, limits the radius of action, and requires frequent washing and renewals.

The relative output of gasoline engines has been so much increased in recent years that a 30 or 40 horse power direct connected generator set now occupies only a relatively small space. The engines also are much more reliable in operation than formerly, and one of the former important advantages of the storage battery is being overcome. The combination system affords the same flexibility of drive as the electric system. There being no positive mechanical connection between the engine and the car, the former is not subjected to road shocks to the same extent as where a mechanical change gear is used. The speed control is also simpler, being similar to that of the electric truck.

The combination truck would seem to have its most promising field in dense traffic and where there are not too many steep grades. Its smoothness of speed control and flexibility are of the greatest advantage in work in crowded thoroughfares. In very hilly districts its relatively greater weight as compared with a gasoline engine combined with a mechanical drive would be a disadvantage. As the ratio of gear reduction from the electric motors to the driving wheels could not be changed en route, very powerful motors would be required to carry full loads up the hills. In New York city the conditions are evidently favorable, and the experiment of the express company may well prove a success.

# Greater Comfort for Drivers.

Most of the 1910 models have been constructed with the idea of making them as comfortable for the operator as possible. Probably control systems have been somewhat simplified so that fewer motions are needed than formerly, but the principal improvements have been along the line of reducing the effort required to make the necessary motions.

To this end a great deal of care and patience has been used in laying out the hand levers for brake and gear control, so that the handles are in the most comfortable position possible. In some cases the movement of the levers has been reduced so that they are easier to reach in the extreme forward position, and there is more clearance for the hand when they are pulled back nearest the seat. Pedals have also been made easier to operate by placing them in more convenient positions, and also by increasing their leverage so that less strength is required. The more convenient location has been obtained by making the pedals ad-

justable in length. By proper adjustment the foot pads may be brought into the most comfortable location for a long or short legged driver.

The most important tendency toward simplification consists in combining the brake and clutch control in one pedal. Where this is done the slight movement required for the clutch may be secured by a cam, so that when the pedal is pressed further forward to apply the brakes the clutch spring is not compressed any more. This cam movement saves the clutch spring, since it is only compressed enough to release the clutch, and relieves the driver from part of the effort often required with single pedal control.

Steering gears are not materially changed. Rather larger steering wheels will probably be used on the average, however, and the columns will be set at a greater angle so that the gears will be more comfortable to operate.

On the whole, we may say that 1910 cars will be the most comfortable to operate of any which have yet been produced. For while in former years the control systems have been carefully worked out on many of the higher priced machines, the coming season will be the first to see such refinements of design applied to all classes of automobiles.

# Recuperation of Our Foreign Automobile Trade.

The past few months have shown a remarkable increase both in the imports and exports of cars, as compared with the same months the previous years. The growth in imports is especially pronounced when numbers of cars are considered instead of values, the average values having materially fallen. Thus, only a few years ago the average declared value of foreign cars imported here was around \$3,500. cars imported in June last had an average value of only \$1,880. It must not be concluded from this, however, that the foreign manufacturers now sell the same cars for little more than half the price they asked only a few years ago. The cars imported are, on the average, of much lower horse power than formerly, and, besides, a considerable number of taxicabs are included in the list. The average imported car now has only a very slightly greater declared value than the average American exported car, the average value of exported cars for June having been \$1,810.

The growth in automobile imports is

readily explained by the great demand for cars in this country this past spring, which taxed the capacity of practically every maker. That American manufacturers, in spite of the demands of the home market, which naturally turned their attention away from foreign fields, should nevertheless have found greater outlets abroad is most encouraging. During June more than four times as many cars were exported as were imported, the aggregate value of the exports being slightly more than four times those of the imports. The automobile movement seems to have taken a strong hold in the Canadian provinces the past year, and as this market is very largely controlled by the American industry it has strongly boosted the export figures. The United Kingdom, too, in spite of the general depression in the motor trade in that country the past year, took a greater number of cars from us than the previous year. The facts about the enormous production in this country are becoming known, and that we are producing nearly twice as many cars a year as all the European states together certainly tends to disprove the much repeated allegation that we are behind Europe in automobile matters. Besides, figures talk. Quantity production enables the large American manufacturer to produce cheaper than his European rival with his relatively restricted outlets. If the customs returns show the average value of exported cars to be only a little less than that of the imported ones, it is a fair presumption that the American cars were on the whole of larger and more powerful type.

The new tariff which went into effect last week leaves the duty on automobiles unchanged, and will therefore not affect the development of our foreign auto trade, As there was at no time any likelihood of any important change in the rate of duty on automobiles it is not likely that the recent increase in the volume of imports was in any way due to the impending tariff revision, but was entirely due to an increase in the demand for foreign cars.

# Economy in Shipping Automobiles.

A number of manufacturers have been making a practice of shipping cars parely disassembled to foreign countries where there is some saving in the duty from shipping this way. This has been customary in shipping to Canada, where a number of as sembling branches have been established. This practice of "knock down" shipping

has not always been successful, for it has been found in some instances that the cost of assembling in the branch was so much greater than that at the factory that the saving in duty and transportation was wiped

It is evident that the shipments to an assembling branch must be sufficiently large and regular to allow of the assembling force being kept busy all the time. Under such conditions the cost of assembling should be little greater than at the main factory.

Some of the large makers evidently believe that conditions in the West and Southwest now promise a sufficiently large and sustained volume of business to warrant the shipping of cars in the knocked down condition, for the establishment of two assembling branches in that section of the country has recently been announced. Recent developments in motor car design are in the direction of economical assembling, and it is evident that as export trade increases and the number of cars shipped to parts of the country remote from manufacturing centres becomes greater, much can be done to reduce the volume occupied by the machines when shipped in the knocked down condition.

Like most other questions of economy in the manufacture of motor cars, all these possible savings are closely related to quantity production; for the cars assembled at a branch must be as carefully inspected and adjusted before delivery as though they were put together at the home factory, to give equal satisfaction to customers.

# An Accident Shop Superintendents Should Take Notice Of.

One of the storchouses of the factory of the Olds Motor Works in Lansing collapsed last Saturday, owing to the pressure of steel castings piled against the walls. The walls were of brick and the weight of the castings forced them outward, allowing the roof to fall. There were three workmen in the building at the time of its collapse. Of these, one was so badly crushed that he died shortly after, and another was so severely injured that his chances for recovery are slight. The third workman was unhurt, being blown through an open door by the rush of air caused by the falling roof.

# Is a Runabout Type Developing?

By F. E. WATTS.

While gathering material for the article on the high wheel automobile which appeared in the issue of June 30, 1909, the writer began to wonder if the high wheel and the low wheel runabouts were not approaching a common type. To ascertain roughly if this were not so, Table I was prepared from the data of a number of 1909 runabouts costing \$1,000 and under.

The averages given in the last line of the table for high wheel cars are those obtained from the article referred to above. A comparison of the averages for the two classes shows that the pneumatic tired car is somewhat longer and heavier, and just a little more horse power, though not quite so much in relation to the weight, and costs a little more. Shaft drive and four cylinder, water cooled motors are the favorite constructions. The sliding gear and the planetary are the favorite speed changing devices.

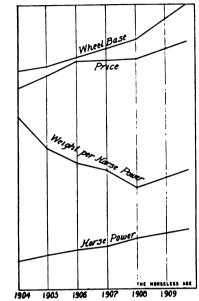

In both classes of cars the development is somewhat similar; both have grown longer and heavier; in both the motors are increasing in power, and, strange to say, in both this season shows an increase in the weight of the empty car per horse power.

The latest tendency in both classes is toward the four cylinder motor and the shaft drive. And the principal divergence is in the wheels and tires, and in the tendency toward air cooled motors on the solid tire cars, while water cooling is almost universal on the pneumatic tired machines.

Reports on 1910 models of high wheel autos have not yet begun to come in, but low priced, pneumatic tired machines, whose specifications have so far been published, show a decided increase in size, power and wheel base. Their wheel bases are about 100 inches, and the average horse power will run well toward 25. Probably these features of the high wheel cars will show an increase, though not so marked.

Present tendencies are thus seen to be

away from the runabout and toward a combination type of vehicle large enough to carry four people, the two rear passengers being carried either in bucket seats or a seat with low continuous back. Manufacturers

CURVES SHOWING YEARLY AVERAGES FOR LOW WHEEL RUNABOUTS.

generally build what is easiest to sell, so it is evident that the greatest demand is for an ambitious imitation of the high priced car. There are no present indications that this demand will grow smaller, but it would appear reasonable to suppose that the cars promised in 1910 would satisfy its every requirement, so far as size is concerned, and that the cheaper cars of the future are likely to be smaller rather than larger.

A glance at the table will show but one runabout which is designed for economical use for business purposes, the Brush. This car and the single cylinder Cadillac, the manufacture of which will very likely be discontinued, have proved very economical in the hands of the average user. The reason for this is their comparatively low power, which makes them slow speed machines. The ability to go fast, or the power to handle four passengers at a lively gait, is demanded by a large class of users for pleasure purposes at the present time, and their demand is developing the types which the tabular figures show. In the high wheel machines, however, considerable power may be demanded so that the car will pull well through heavy roads rather than from considerations of speed. But no matter what purpose it is required for, power and weight increase the operating cost, so there is bound to be a renewed interest in the smaller car at a later date.

We may conclude, then, that from present indications the small American cars of both classes are approaching a compromise type, which will be somewhat similar for both classes—it will be suitable either for a runabout or a four passenger machine for light touring. While this machine will be just what a large class of users want, there remains a market for a smaller car, which is likely to be only partially supplied for some years to come.

The following table shows the average dimensions for runabouts for some years past:

		Average Wheel		FOR LOW W	HEEL RUNABOU	т\$.	Pounds

# Maintenance and Repairs

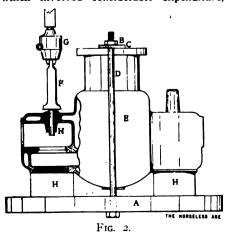

# Restoring a Broken Valve Guide. By Oliver Light.

A certain motorist of the writer's acquaintance recently had an accident which at first sight seemed to necessitate a costly replacement, but after closer investigation a very practical repair was made at comparatively slight cost. In attempting to remove a slightly bent valve, which had stuck in its guide, for inspection and grinding, the valve stem guide bushing was sev-

ered from the valve chamber of which it formed an integral part, as shown at A, Fig. 1. Through lack of knowledge the motorist was put to a certain expense which would never have been incurred had he intrusted his work to a capable machinist. To straighten the bent valve stem (exaggerated in the sketch), a sharp blow with a moderately heavy hammer was directed at the end C in the direction of the arrow, and, as nothing had been placed at the end of the valve stem guide to take the force of the blow, the cast iron guide broke off very close to the valve chamber. As must be evident, the steel valve stem was able to exert considerable leverage at the point A, especially when the guide had worn appreciably.

After being told by the agent of the car that a new cylinder was the only remedy, which involved considerable expenditure,

the motorist took the writer into consultation, to see if the cylinder, otherwise in perfect shape, need be replaced. There was too little of the guide left in the interior of the valve chamber to insure accurate seating of the valve, and the engine operated very unsatisfactorily at anything but low speeds. The writer applied a new bushing or guide to replace that broken. and while there can be no claim for the exercise of any great ingenuity or original. ity in this method of making a repair, it is believed that the manner in which it was accomplished may be of some interest to those not specially skilled in "patchwork" repairs.

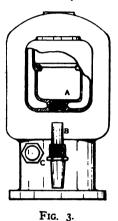

The first operation was facing off the irregular metal on the bottom of the valve chamber, which was done by a simple facing tool as shown at Fig. 2. This was forged from a piece of tool steel. The lower portion was turned 7-16 inch in diameter, and the upper part so that it would go into the chuck of a back geared drill press. As the guide hole for the stem was worn considerably (having been originally about 36 inch in diameter), the hole was first cleaned out with a 7 inch drill, to form a guide for the lower portion of the facing tool. The cylinder E was firmly clamped to the drill press face plate by means of two long through bolts D and the strip of steel bar C, which extended across the mouth of the cylinder, and was held in position on the parallel blocks H by the nuts B. After the metal had been removed from the bottom of the valve chamber, which was faced flush, the cylinder was reversed, and again clamped in position. Then the facing tool was used till all of the projection H had been removed. An 11-16 inch drill was then placed in the chuck G and a large hole drilled through the metal at the base of the valve chamber. following the  $\frac{7}{18}$  inch hole as a guide. The cylinder was again clamped in the position shown in Fig. 2, and, using a centre in the chuck bearing against the depression in the top end of a 34 inch 32 thread tap to insure a straight thread, the hole was tapped out. turning the tap with a spanner placed on the squared portion, the chuck being fed down as the tap progressed in the hole.

The next operation was turning up a suitable guide, which was done in a lathe. using a piece of bronze bar stock which was available. On this was left a substantial shoulder, and a greater length of threads than had been tapped into the valve chamber metal was cut on the bushing, in order that a check nut could be employed to make a sound job. The bushing was not bored, as there was some chance that the hole A, Fig. 3, had not been bored out true, which would throw out the valve seating. The bushing is shown at B, Fig. 3. and the check nut at C.

The threads on the bushing B had been cut a little larger than those in the hole A, and the bushing was screwed in place with but little difficulty by the use of a large spanner, the check nut being applied

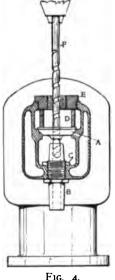

with a socket wrench from the top. To prevent backing out, the metal protruding above this was upset with a centre punch, this making a very strong construction; in fact, of greater resistance to both wear and shock than the original cast iron bushing which it replaced. This bushing is shown in position in Fig. 4.

The method employed to insure that the hole through the guide would be in the proper relation to the valve seating is also of interest. A spare valve was at hand, so the old one with the bent stem was discarded. The head was cut from this, after it had been thoroughly ground in to a correct seating, and a portion of the stem. where it flared out to join the head and

obviate an abrupt bend, was left on. The valve head was accurately centred in the lathe chuck, and the centre mark, which had acted as a support for it when it was first machined from the forging, formed an accurate guide by which a 36 inch hole was drilled exactly through the centre of the head. The head was then held in position on the bevel seating by means of a piece of tube, accurately faced off at both ends, which was in turn retained by the valve cap. The valve cap E was tapped for a spark plug, and as the tube D held the valve head A positively in place, a guide was obtained for the twist drill F, and the 36 inch hole for

the valve stem bearing was drilled so ac-

F1G. 4.

curately that the new valve had a perfect bearing at all points on the seating.

While there is no reason to doubt that a very satisfactory job would have resulted if the thread had been eliminated and the bushing made a driving fit into the bottom of the valve chamber, which had a thickness of metal of about 5% inch, it appears to the writer that the more positive retaining power of the thread and checknut amply compensated for the increased expense in machine work. This job took seven hours, and cost but \$4.50, which included the bronze stock. This material was used because it was handy. The ease with which it may be machined, and its strength, about equal to that of mild steel, which obviously machines harder, were other advantages in its favor. In presenting the illustrations no attempt has been made to show proportions, it being the writer's object to show principles and their application more than actual construction.

# Breaking of Poppet Valves: Symptoms, Effects and Temporary Repairs.

BY THE TROUBLE MAN.

Thanks to the better proportioning of valves, the use of materials better adapted to the purpose and the adoption of cam profiles which secure seating at low velocities, the breakage of valves, in service, is now much less common than formerly. The adoption of mechanically operated inlet valves has also tended toward this condition, breakages being much less common with this type than with valves opened automatically by engine suction and seated by springs. A similar course of refinement has rendered valve springs comparatively immune from sudden failure.

However, both valves and valve springs do occasionally break on the road, and it is well to know what to do when this happens.

# INLET VALVE.

A sudden and almost continuous popping in the carburetor is the usual indication of a broken inlet valve and when this is noticed the motor should at once be stopped, if indeed it does not stop of its own accord. Prompt shutting down is extremely advisable, for there is a chance that if the motor is kept running the head of the valve or a portion of it may be drawn through the inlet port into the cylinder, and be caught between the piston and cylinder head, on the up stroke, fracturing one or both of these parts. Some engines, however, have bridged inlet ports which tend to prevent the drawing in of the valve and the consequent occurrence of such an

If an inlet valve has actually broken the cylinder in which it is located may readily be identified by its lack of compression, when the motor is cranked over with the spark shut off. The removal of the cap over the suspected valve will finally settle the question as to whether the valve is

broken or whether it has only stuck in an open position, through the breakage of the spring or binding of the stem in its guide.

BROKEN SPRINGS.

Spring breakage is perfectly obvious upon inspection, and if the valve stem is stuck it is necessary to work some lubricant into the guide or even to remove the valve and smooth its stem by draw filing.

If a new valve or spring is required and the spare parts are at hand it is of course necessary to remove the key holding the spring and to withdraw the broken valve through the valve chamber opening above it. This sounds easy, but it is by no means a pleasant piece of work when the engine is hot, especially as the valve springs used are generally very stiff and unmanageable, and it is often no easy matter to withdraw the key which frees the spring. Special valve spring tools are made which greatly facilitate this operation, and it is well to be provided with one. The breakage of an exhaust valve of a force cylinder engine is generally indicated by the loss of power due to the failure to operate of the cylinder to which it belongs and sometimes muffler explosions occur.

#### EFFECT ON OTHER CYLINDERS.

Lack of compression upon cranking will determine in which cylinder the trouble exists. If the breakage of an inlet valve only affected the cylinder to which it belongs it would generally be possible for one to proceed to his destination by the power developed by the three undamaged cylinders. Unfortunately, a broken inlet valve frequently puts the whole engine out of commission. If the inlet valve of No. 1 cylinder breaks this cylinder will be open at all times to the inlet manifold. When its spark occurs the cylinder is full of gas, not compressed, to be sure, but explosive, and the combustion extends freely through the manifold and down to the carburetor, filling the intake piping with burnt gas. The inlet valve of cylinder No. 2 may be open at the time of the explosion in No. 1, although it is nearly at the end of its suction stroke. and its charge is likely to be fired prematurely by the explosion above noted.

When the exhaust valve of cylinder No. I (the defective one) opens, the exhaust manifold and the inlet manifold are in connection through cylinder No. I. Cylinder No. 4 is drawing its charge at this time, and it draws partly through the inlet manifold and carburetor and partly through the inlet manifold cylinder No. I and the exhaust manifold. The result is a foul charge which may be below the limit of inflammability.

Cylinder No. 3 is drawing its charge during the power stroke of the damaged cylinder (No. 1) and there is likelihood that its charge will be fired by the flame of the explosion in No. 1, if indeed the gas drawn by No. 3 is not too much fouled to burn. If one is unfortunate enough to be unprovided with the required repair parts it may become necessary to put the engine into some sort of running condition in order to reach a repair shop.

CUTTING OFF IGNITION.

If the ignition of the cylinder which has the broken inlet valve (No. 1) is cut off, there will be no explosions in the manifold and carburetor, and cylinder No. 2 will operate normally, as will cylinder No. 3. The spark plug of No. 1 should not be removed, in order to bring this about, as then the intake system would be open to the outside air through the plug hole and the charge drawn by the cylinders would be too weak to be fired. To cut off the ignition from the defective cylinder, if vibrator coils are used, a piece of paper should be placed between the vibrator points of the coil which sparks this particular cylinder. If a high tension magneto be the current source the high tension terminal should be detached from the plug and fastened to some grounded portion of the engine.

Cutting off of the ignition from the defective cylinder will not, however, improve the operation of cylinder No. 4, which draws exhaust gas through cylinder No. I on its suction stroke. This can be prevented, however, if the cylinders have individual inlet connections, by loosening the intake pipe connection of the damaged cylinder and slipping a piece of cardboard or tin under the flange so as to cover the opening of the intake branch and then setting up the flange tightly. The damaged cylinder will then be entirely cut out, as it were, and will not affect the others. After this is done the spark plug may be removed from this cylinder in order to do away with loss of energy caused by compressing the gas in cylinder.

As a rule valve breakage consists in the fracture of the head or its separation from the stem. When this occurs the head can be removed from the pocket to guard against possible mechanical damage and the stem left in place. If, however, the stem has to be removed, the hole which forms the guide must be tightly closed with a wooden plug, firmly driven in. Unless this is done the air leak permitted will weaken the charge so that the motor cannot be started.

The breakage of an inlet valve in a two cylinder opposed motor will usually not prevent the other cylinder from running, if ignition is cut off from the defective one.

EFFECTS ON FOUR AND SIX CYLINDERS.

The results of breaking an exhaust valve on a four cylinder engine are not so serious as those arising from the failure of an inlet valve. The operation of the other three cylinders is not much affected. It may be as well to remove the spark plug from the inoperative cylinder, however.

In the case of a six cylinder engine the breakage of either an inlet or an exhaust valve disturbs the operation of other cylinders than the one having the defective valve. If the repair parts are not at hand the absolute cutting out of the defective cylinder, by blocking the passage to the broken valve, is required. It is best always to have an extra valve and spring in the repair kit, as driving with one inoperative cylinder is far from pleasant.

# Shop & & Equipment

# Novo Superior Steel.

Most of us who are interested in shop methods remember the revolutionary increase in the speed with which stock could be removed which followed the introduction of the "high speed steels" a few years ago. So great was the increase in feeds and cutting speeds that many machine tools had to be redesigned to meet the new require-

A short time ago some of the pioneers in the introduction of "air hardening" or "high speed" tool steels announced that they had perfected new brands whose performance put the old ones in the shade. Typical of these new steels is the "Novo Superior," handled by Hermann Boker & Co., of New York and Chicago. This is claimed to stand a considerably higher cutting speed than the older steels, varying from 50 to 60 per cent... higher on soft material to about 25 per cent on hard material. It is said to cut harder material than any other steel yet produced. Under the same conditions of feed and speed a tool of this new material is claimed to run from four to six times as long as one made from other steels without need of grinding. These performances have been shown by public tests.

The steel should be forged at a very light red or yellow heat. After rough grinding the tool is slowly heated to a dull red, then the nose is quickly brought to a full white welding heat and quenched in thin oil, For cutting specially hard material cold water or brine is used in place of the oil.

The experienced shop superintendent will be rather slow to believe in the cutting qualities claimed for these new steels until he has seen them equaled in his own shop. But reports from various factories indicate that the public tests have been verified in private use. If these reports prove true the use of chrome-nickel and other alloy steels for automobile parts may become more common.

Some Grinder Improvements.

The latest grinders made by the Pratt & Whitney Company, 111 Broadway, New York, contain some novel devices designed to aid in getting out work more rapidly and more accurately. One of these is a new form of back rest, which they term "the self feeding and unyielding back rest." As shown by the illustration, this supports the work at an angle of about 45 degrees. The jaws are adjusted to fit the work when it is largest and are automatically fed in as the work is ground to size, maintaining a uniform contact. In the earlier models this was accomplished by horizontal and vertical screws operated by coiled springs. In the model shown, however, a single feed

PRATT & WHITNEY SELF FEEDING AND UN-VIELDING RACK REST.

at an angle is apparently used, and this is operated by a weight. The back rest jaw is automatically locked in the position to which the weight feeds it by the roller moving in the slot in the arm above. A series of jaws are provided for different sizes of

It is claimed that by the use of this back

PRATT & WHITNEY SIZING DEVICE.

rest the grinding wheel is kept true much longer than ordinarily, and hence wears longer, since but little of the material of the wheel is wasted.

Another improvement is the automatic sizing device. The grinder has two feeds, a coarse feed for roughing nearly to size and a fine feed for finishing. When the piece is roughed near enough to size the fine feed is automatically thrown in by an electrical device, operated from an arm which rests upon the work. Traveling at this fine feed the wheel is automatically fed in until a micrometer screw, which has previously been carefully adjusted, makes a second contact. This second contact stops the radial feed. It will be seen that the work will be ground to the desired diameter its entire length, no matter how much the wheel wears. Also that any number of pieces can be turned out in duplicate.

If it is desired to grind only a few pieces of a given size, so that it would not pay to use the sizing device, the machine can be operated with mechanical feed, similar to other grinders.

# A Unique Slabbing Job.

It is sometimes possible to do extra work on a piece without taking any extra time. A good example of this is the attachment

REAR VIEW, SHOWING DRIVE. SLABBING ATTACHMENT FOR NATIONAL ACME AUTOMATIC SCREW MACHINE.

plainly shown in the accompanying cuts. It was furnished the Cadillac Motor Car Company by the National-Acme Manufacturing Company, of Cleveland, O., and was attached to their No. 53 automatic screw machine.

The piece on which the slabbing is done is threaded at one end, and the slabbing is performed while the piece is held stationary for the threading, hence it takes no additional time. The milling cut is made by two straddle mills on a vertical shaft, which is driven by bevel gears from a horizontal shaft that carries the driving pulley. This last is driven from a special countershaft in the machine shown, but could be driven direct from the die spindle gears. The attachment is fastened to the top of the cut off tool slide. It is stated that these pieces are made at the rate of 53 an hour.

# Automobile Insurance.

By J. E. JENNINGS.

At one time the insuring of automobiles was looked at askance by insurance companies. There was a day when no stock company would write automobile risks. The underwriters who took these risks made no money on the business or suffered heavy losses. This is no longer the case. as the number of strong companies that write this form of insurance is steadily on the increase, and, moreover, they have extensive agency connections that keep them in close touch with that part of the public that goes in for automobiling and wishes to lose nothing by its passion for the new means of locomotion, if insurance will enable it to do so.

Formerly a foreign institution, which balks at no risks if there is a possible chance of making money, was the mainstay of the automobilist who was looking for insurance from peril by land-fire or casualty or collision. With the improvement of the automobile came less danger, or less chances of the underwriter losing, and the number of those owning machines who determined to be at no loss if there was a possibility of arriving at that happy end also increased materially. Gradually the home (or American) companies came into line, determined upon sharing the profitable field with the foreign insurance concern (the London Lloyds), until now there is a very respectable array of talent cultivating a paying field. The names of some of these companies were recently printed in THE Horseless Age, with a list of their rates

The interest of the underwriter in this direction is not abating by any means. The Providence-Washington Fire Insurance Company has recently established an automobile department for the purpose of insuring automobiles and motor vehicles against fire, theft, collision and transportation hazards under what is termed in insurance parlance a general floater form. Indemnity for collision is covered under a rider, with an additional charge. The old established Hartford Fire Insurance Com-

pany has made arrangements to handle its automobile department through special agents separate from the fire department.

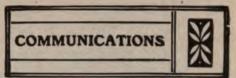

NO LIABILITY INSURANCE IN IOWA.

The man possessed of the speed craze is not to be encouraged in his madness. It is noted that the insurance department of the State of Iowa has just delivered itself of an utterance to that effect. The department's ruling is that liability insurance companies will not be allowed to issue policies protecting the owners of automobiles against suits resulting from injuries caused by their machines. The department holds that such form of insurance is contrary to public policy, in that it has a tendency to encourage careless driving and excessive speed, and that liability insurance may be taken in the future only to protect freight automobiles. The "automobile hazard" is not likely to decline in frequency. At the recent meeting of the International Association of Accident Underwriters, at Niagara Falls, it was stated that within the year 1,663 claims for damages for accidents were made on the companies by owners, passengers and chauffeurs, involving twenty-six deaths, and that one in every sixty-four accidents is fatal. There were 1,635 injuries involving 3,798 weeks of total disability and 4,307 weeks of partial disability.

Automobile insurance, whatever its form—fire, collision or casualty—is a pretty good form of investment. It is not exactly like that of life insurance, which so many people look upon as they would regard in vestments in houses or lands, or stocks and bonds, but it is one that will pay. Of course gains cannot be made by it as from the other forms of investment alluded to, but there are so many possibilities to be guarded against that it behooves every owner of an automobile to protect himself, just as he insures his house, or garage, or his life. And in saying this there is no axe to grind.

Automobile insurance is in its infancy, but it will attain sturdy growth. The insurance man may be depended upon for an intelligent campaign of education in this line, an education which shall force upon the attention of every automobile "risk" the knowledge that insurance is one of life's necessities to the automobilist. Insurance against disaster is a form of insurance which comes nearer to being one of the absolute necessities of the automobilist than any other. With so many strong insurance companies in the field it is safe to say that the automobiling public will not be long left in ignorance of the benefits of the forms of insurance they have to offer. Any policy indemnifying for disability or damage is a necessary, businesslike precaution, and the insurance companies now looking for business in the automobile field are such as command the confidence and support of their clients.

The stock capital of the Fiat Automobile Company, in Turin, Italy, has recently been increased from 9,000,000 to 12,000,000 lire.

# Manufacturer's Comments on Glidden Tour.

Editor Horseless Age:

Now that the Glidden Tour is over, and the manufacturers and contestants have had an opportunity to view the event from a commercial as well as a sporting standpoint, they cannot help but arrive at two conclusions:

First, that the tour was a great success in the development of the business in the section of the country through which it passed, and that it should be repeated; and, secondly, that for the coming season the rules covering the run should be more strictly and scientifically drawn than they were this year.

For instance, in this year's run cars made a perfect score and yet experienced considerable difficulty, as no penalizations were imposed for adjustment of carburetors, ignition troubles, oiling or adjustment of brakes, and cars were allowed to be towed; and fourteen of the entrants, including some six cylinder cars and prize winners, were towed. Had the rules this year taken these matters into consideration, the cars would have ranked quite differently at the end of the run.

We believe that ignition trouble is one of the most serious difficulties to the average automobilist, and one which is the cause of more stoppages than any other one thing. Undoubtedly, also, the oiling system is of the utmost importance to the entire life of a car, and any event of the nature of the Glidden Tour should put the oiling system to the severest test.

Dependable brakes of long service are what every motorist wants, and that a perfect score car could go through making frequent adjustments to the brakes without penalization we do not feel is just right. Without detracting from the splendid performance of the perfect score cars, we cannot help but wonder what the result would have been had the rules been drawn up in a more technical way and with less favoritism to the large cars.

Our own entries, which won Class D, cars selling from \$1,000 to \$1,750, were lost sight of in the placing of the final awards, and the public were made to feel that nothing but the high powered and expensive cars were capable of winning such an event, whereas our cars made the entire run without adjustment of carburetor, ignition or oiling system, and it was not necessary to even tighten the brakes, and we were not towed up any hills. The light weight of our cars reduced our tire trouble to a minimum, we having only two punctures, the same casings carrying the cars through the entire trip. It must be borne in mind that these cars carried the same number of passengers as the larger and more powerful

cars, so that the total cost per passenger was very much less than that of any of the larger and more expensive entrants.

We trust that next year you will use your influence to make the run even more strenuous than it was this year, a trip from the Atlantic to the Pacific, we believe, being the most advisable, and that the rules be gotten up in a way to give the lower priced cars the same chance as the high priced ones.

MAXWELL-BRISCOE MOTOR COMPANY.

# Cause of Difficult Starting. Editor Horseless Age:

I have a 36 horse power, four cylinder gasoline car and occasionally make the mistake of killing the engine by pulling it down, in which event it is a very hard job to start it again. Cranking with the spark off and then with the spark on doesn't seem to help. Ordinarily the engine starts very readily and after standing for a few hours nearly always goes with a half turn of the crank. What is the trouble and how may I avoid it?

CHARLES E. CRISMAN.

[Probably your carburetor is so adjusted as to give too rich a mixture under the conditions which stall your engine. Such a fault would not only tend to make the engine stall easily but would make it hard to restart, for the excess of gasoline present in the cylinders makes a mixture too rich to ignite. A few turns of the crank with throttle closed and relief cocks open should clear out the excess of gasoline and restore normal conditions, when the engine should start with its usual ease.

The proper adjustment to remedy this defect depends upon the type of carburetor. If it has an auxiliary air valve, the spring probably holds the valve to its seat with too great an initial pressure. If adjusting the spring to relieve this pressure gives too weak a mixture at high speeds a new spring may be necessary. If your carburetor is of the puddle type, slightly reduce the depth of the puddle by bending the float arm downward.—Ep.]

# Offsetting Cylinders.

Editor Horseless Age:

It would seem that Hugo C. Gibson in criticising the article on "Offsetting Cylinders" and the results obtained was misled by the fact that my article was cut down, and he assumed that the method used to get results was wrong. Mr. Gibson is not to blame for the fact that the article was not complete as published. He concludes that 80 degrees spark lead must mean that the charge was polluted. He is wrong in this, however. While the apparent spark lead is 80 degrees, the contact period is 8 inches on the same 13 inch circle, so that the actual lead as indicated by the centre of contact was only 43 degrees. As to the state of the charge, the power developed would indicate that it was O. K. As to the position of the spark lead ahead and from the true dead centre, it was accurate. The dead centre was located by trammeling the engine, using the lower edge of the piston and carburetor port as a gauge point, so that the true dead centre is a point where the piston pin, crank pin and crank shaft centres are in a straight line. The same is true on both top and bottom dead centres. It is sometimes held that the piston of an offset engine is in dead centre when the connecting rod is parallel to the centre line of the cylinder.

As to the effect on the port timing there is no gain by offsetting when viewed from the proper standpoint. Mr. Gibson ventures the opinion that no tests are of value unless the engine speed is, say, 1,500 r. p. m. He might as well reason that if an engine does not run at 1,500 r. p. m. it is not suitable for automobiles. The engine used in the tests was of the marine type, rated at 4 horse power at 900 r. p. m., and does good work at that speed, while at the speed suggested it would be useless to attempt to drive a launch with the propeller coupled up direct to the shaft. As to the claim that "offsetting decreases in value as a friction remover as the speed increases,' this is a new theory to me. If he can quote any authority who can prove it to the readers of THE Horseless Age and myself I think it would be interesting. A high speed engine test will perhaps prove the claim as to lack of balance. (See THE HORSELESS Age of October 28, 1908, page 578, where it is stated that the Daimler Company discarded the feature on that account.)

JAMES McIntosh.

# Motor Truck for Carrying Lumber. Editor Horseless Age:

Could you inform me through the columns of your paper if there is a motor truck on the market fitted with a body adapted to carrying lumber, i. e., planks and joists 20 to 30 feet long? Dumping cannot be done with an ordinary open body and much time is lost unloading piece by piece. I have failed to notice in the various advertisements and manufacturers' catalogues mention of a truck of about two tons capacity supplied with a quick unloading body, and would appreciate any information you could give me on the subject.

F. H. D.

[Truck manufacturers usually build the bodies to order to meet the user's requirements. We cannot recall at the moment any instances of the use of motor trucks for lumber hauling, except in the forests of Maine, and there, we believe, no special loading means are used. It would seem to be a relatively easy problem to construct a special body that would dump sideways, being strongly hinged on one side and provided with rails or guides which would cause the logs to fall clear of the wheels, the other side of the body being raised by means of a derrick or hoist operated by the vehicle motor. If any reader knows of a body suitable for logs that can be dumped in some such way we should like to hear from him.—ED.]

### Queries.

Editor Horseless Age:

As a reader of your journal I would like to see a report of the investigation, or, rather, experiments, made with different kinds of rubber tires in the sand near Detroit, Mich., a short time ago to determine the best tire for sand.

Will a four cylinder engine give better service than a two cylinder of the same horse power on very sandy roads when the pulling is heavy all the time? Will a double opposed, horizontal motor produce the same power as a vertical of the same horse power? How do steam and gasoline engines compare where roads are sandy and the pulling is heavy? Is an engine overloaded when it can propel the car, or is it better to have a surplus of power? Is it as liable to overheat with the surplus power? Which will give the best continued service? What would be the best ratio of gear, 3 to 1 or 4 to 1, where it is not a question of speed but good service? heavy pulling make engine smoke? Are you getting good service and mileage when the engine is smoking? J. DRACE

[The first of your questions cannot be answered directly, but the following answer may serve your purpose. If you have a four cylinder engine and a two cylinder engine, both giving substantially the same horse power at the same speeds of revolution, and if both were geared to the rear axle with the same ratio of gearing, then both should pull equally well in sand. The four cylinder would undoubtedly hold up to the work better at very low speeds. awing to the fact that the minimum speed of operation under load is usually less with four cylinder motors. This is all a matter of flywheel capacity, however. should be absolutely no difference between a two cylinder opposed and a two cylinder vertical motor, especially if the two cylinder vertical has only a single crank throw, so as to evenly space the explosion, the same as the opposed motor. The stem power system is more flexible and per of producing much more power for that periods than continuously. For this reason the system is particularly suitable where very steep hills are encountered occasionally, or deep sandy stretches. An engine is overloaded when it is pulled down in speed to such an extent that there is knocking in the bearings. It is hard on any engine to work it continuously near its maximum power, and it is better to have a somewhat larger engine on the car. The larger motor will not overheat so easily as the smaller one, provided the radiator capacity is in proportion to the horse power ratings. The larger engine will give the best continuous service, provided the car is not driven as fast as the larger engine will allow it, but is throttled down where the draft is light. If the roads in your vicinity are sandy it is much better to use a 4 to 1 than a 3 to 1 gear. You would, of course. not be able to go quite so fast on level roads with the 4 to I gear.—En.]

# NEW VEHICLES AND PARTS ➤ ➤

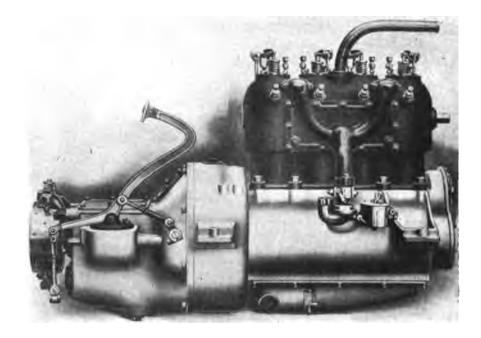

# Chalmers-Detroit 1910 Models.

There will be two chassis models of Chalmers cars for 1910. Both will be practically continuations of last year's models, but will be considerably larger cars. In mechanical construction they are almost identical with the cars announced a year ago, but exhibit that refinement of detail which comes with additional experience. These two chassis will be fitted with a variety of bodies sufficient to suit all tastes.

THE "THIRTY."

The motor of the new "Thirty" is 4x41/2 inches, which is one-eighth inch larger bore than the 1909 model. All the typical constructional features of last year's motor have been retained. The large diameter crank shaft mounted on two annular ball bearings, the barrel crank case of aluminum, the four cylinders cast together, block fashion, with inlet valves overhead and exhaust valves at the side, are the same as on the 1909 model in their general design. The inlet valves have a clear diameter equal to one-half that of the cylinder bore, and the exhaust valves have been considerably enlarged, being now 17% inches in clear diameter. The exhaust manifold increases rapidly in size from the forward cylinder to its junction with the pipe to the muffler, which is remarkably large, forming the best combination the writer has yet observed for clearing the cylinders.

INTAKE SIDE OF "THIRTY" UNIT POWER PLANT.

The inlet manifold is still cast with the plate, which covers one side of the water jacket for the cylinders, thus heating the entering charge enough to thoroughly gasify the fuel.

As in the 1909 car, lubrication is by splash from an oil pool whose level is maintained by a pump which circulates oil from a tank below the crank case through a large sight feed on the dash. Instead of the gear pump formerly used for circulating the oil, a plunger pump is employed on

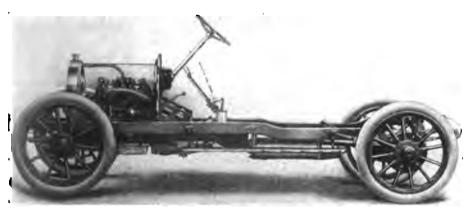

this model. Its barrel is placed in a horizontal position and the plunger is operated from the rear cam. This makes all parts of the pump extremely accessible.

The water is circulated by a centrifugal pump. The fan has been improved by the addition of a rim connecting the ends of the blades. A new type of carburetor is employed, with ball valves for the auxiliary air. The ignition wiring is noticeable for its neatness. All the terminals are brought through the dash from the back of the coil in porcelain insulators.

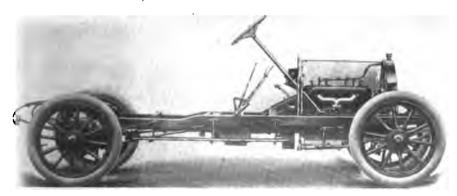

The multiple disc clutch is retained exactly as in 1909. The change gear case is still bolted to the rear of the crank case, so as to enclose the flywheel and clutch. This gear gives three speeds and a reverse selectively. The gears are of carefully heat treated chrome-vanadium steel. The shafts are short and are mounted on annular ball bearings. The final drive is through a single universal joint. This joint is enclosed in a metal case and is steel bushed throughout. A torsion tube surrounds the propeller shaft, but the car is driven by the forward part of the rear springs.

The rear axle is of the full floating type with annular ball bearings throughout. A four pinion bevel differential is used. The front wheels are also mounted on annular ball bearings. The front springs are semi-elliptic and the rear are three-quarter elliptic. The springs have been slightly improved from last year. Grease cups are fitted on all working parts. The rear links have both sides forged together with a connecting band which keeps the links from turning wrong end up when going over unusually rough roads.

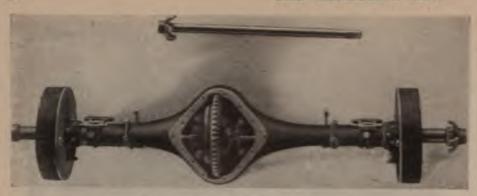

Expanding brakes act on the rear wheel drums and a contracting brake is placed at the rear of the change gear. This location brings it up out of the dust and mud,

EXHAUST SIDE OF CHALMERS-DETROIT "THIRTY" CHASSIS.

CONTROL SIDE OF CHALMERS-DETROIT "FORTY" CHASSIS.

REAR AXIE

and equalizes the action through the differential. The operating rods for the wheel brakes are carried inside the frame.

Steering is by the same worm and sector gear used the past year. The gear shifting mechanism has been slightly improved, and the levers are inclosed in a tight case. The single pedal for clutch and transmission brake and the side swinging accelerator are retained.

The frame is dropped just in front of the rear axle, and rises again at the rear of the front seat. This allows of placing the doors and the tonneau floor lower, and so lowers the centre of gravity of the car. The upper and lower flanges of the frame are tapered, being much wider near the middle than at the ends. This gives considerably greater stiffness, even with the increased wheel base.

The hood has been raised and lengthened to conform with the increased size of the car. The wheel base is 5 inches longer than last year, being now 115 inches. The regular tread will be standard, but 60 inch tread will be optional. The wheels are 2 inches larger in diameter than last year, being 34 inches, and fitted with 33/2 inch tires.

### THE "FORTY."

The principal changes in the "Forty" are those made advisable by the lengthening of the wheel base, and the enlargement of the touring body to give room for seven passengers. The motor is still 5x43/4 inches, with valves all on one side. The three bearing crank shaft and pump circulation of oil have been retained.

No important change has been made in the leather faced cone clutch, but a double reduction of levers is used in the operating mechanism so that only about one-third the foot pressure formerly required is needed to disengage it. The position of the change gear shafts has been reversed, so that the lay shaft is now at the bottom. In the new car the gear shafts run in annular ball bearings.

Two universal joints are used in the propeller shaft. The torque tube on this year's car is made from two tubular members forming a triangular construction with a ball joint at the forward end, cushioned on helical springs. The rear axle casing is of pressed steel, autogenously welded in the neutral plane. The axle is of the floating type with bevel differential. Timken rings are used throughout.

The frame construction is similar to that on the "Thirty." The radiator has been changed from the tubular to the cellular type. The wheel base has been increased from 112 to 122 inches, while the wheels are 2 inches larger in diameter, being now 36 inches. The accelerator lever on the

STEERING CONNECTIONS.

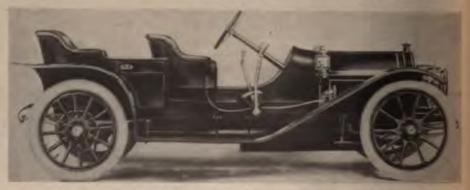

new "Forty" is of the swinging type, similar to that used on the "Thirty."

# BODIES AND EQUIPMENT.

The "Thirty" is furnished with touring, pony tonneau, roadster, inside drive coupé, limousine and landaulet bodies. In the touring body for the "Forty" two additional seats are furnished at a slight extra charge. Pony tonneau and roadster bodies are also furnished. Special arrangements have been made for purchasing extra equipment in quantities, and supplying the same to customers at low prices.

The Acme Roadster.
The Motor Buggy Manufacturing Company, of Columbia Heights, Minneapolis. Minn,, are building a four passenger car of the high wheeled type, for which they have chosen the trade name "Acme." The car is equipped with a double cylinder opposed motor of 51% inch bore by 41/2 inch stroke, and is rated at 22 horse power. A float feed automatic carburetor is provided and the ignition is by jump spark with double coils and dry cells and a storage battery. The motor is water cooled, the water being circulated through a brass tube, flanged radiator. The change speed gear is of the planetary type, enclosed in an oil proof casing, and gives two forward speeds and one reverse. It drives a countershaft from which the power is transmitted to the rear wheels by side chains, Diamond roller chains being used. The differential gear on the countershaft is of the spur type.

The frame is built up of 2 inch by 1/4 inch angle steel and supported by 40 inch semielliptic springs in front and 38 inch full elliptic springs in the rear. Both front and rear axles are solid forgings of 114 inch square section. The car has a wheel base of 97 inches and standard tread. Artillers type wheels are used, the front ones being 36 inches in diameter and the rear ones 41 inches, and solid rubber tires of from 11/2 inches to 2 inches width can be fitted. All of the road wheels run on roller hearings and the same type of bearings are used in the countershaft. The reverse gear of the transmission may be used for braking purposes, and in addition a pair of internal hub brakes are fitted. Both sets of brakes are pedal-operated. Steering is accomplished by means of a hand wheel, which is located on the left hand side of the car, through a worm and sector mechanism. The car weighs 1,500 pounds and a gasoline capacity of 12 gallons is provided. The speed is said to range between 1 and 25 miles per hour. The car has a road clearance of 17 inches. By removing the rear seat a delivery box can be fitted in which loads of 500 pounds or more may be carried.

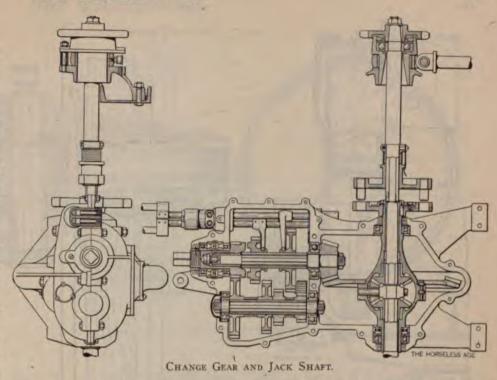

CHALMERS-DETROIT "THIRTY" PONY TONNEAU.

# Alco Three Ton Truck.

The American Locomotive Company, Providence, R. I., have placed upon the market a three ton truck which is the culmination of a series of experiments during which five different models were built. The elimination of the weak and undesirable elements in these models is said to have resulted in a thoroughly reliable design. Its general features, as disclosed by the half-tone cut, are those common to a number of trucks now on the market, but automobile engineering is now a matter of carefully worked out details, and in this respect the Alco truck will repay investigation.

The motor, situated under the driver's seat and footboard, is not only accessible by removing the footboard and opening the side doors, but may be removed from the chassis by sliding it forward after removing the radiator and front cross member of the frame and disconnecting various pipes and control members, all of which, it is claimed, can be accomplished by two men in less than half an hour. The motor has four cylinders of 3 15-16 inch bore and 434 inch stroke, cast in pairs, and its speed is limited by a governor to 1,000 revolutions per minute, at which speed it develops 24 horse power. The crank shaft is made of a special alloy steel, suitably heat treated, the experience of the American Locomotive Company having demonstrated that the best of material is necessary in the working parts of a motor used in commercial vehicles. Hand holes are provided in the upper half of the crank case through which the crank shaft bearings may be inspected; to make adjustments, however, it is necessary to remove the lower half of the case. The cam shafts are made from special steel, with the cams integral, hardened and ground to a master cam. The valve plungers

and rollers are also hardened and ground, and the valve heads are made of high nickel steel. The hollow wrist pins are hardened and ground and are secured in the piston by the threaded taper pins shown in the cut. No means of locking this pin is provided, but it is said never to come loose, an indication of conscientious work-manship.

Lubricating oil is drawn by a gear pump from a reservoir cast integral with the lower part of the crank case cover and delivered to the main crank shaft bearings, from which the crank pins are oiled through holes drilled in the shaft. The excess oil flying from the connecting rods supplies the cylinders and cam shaft bearings. A Bosch high tension magneto with fixed advance is the source of ignition current.

A multiple disc clutch is housed in the flywheel, the discs, alternate ones of which are of steel and bronze, being lubricated by an oil bath.

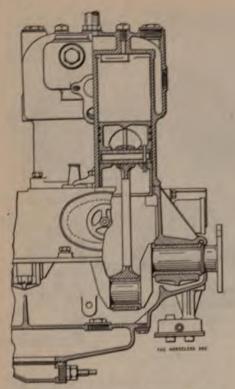

A three-speed and reverse selective gear is used, supported on three points, with Hess-Bright bearings and 3½ per cent. nickel steel gears case hardened and drawn to reduce brittleness.

Both service and emergency brakes are situated side by side in wide drums, forged integrally with the large sprocket and are faced with Raybestos. No attempt is made to protect the brakes from mud and dust.

Timken bearings are used it all wheels.

AMERICAN LOCOMOTIVE THREE TON TRUCK.

SECTIONAL VIEW SHOWING ENGINE DETAILS.

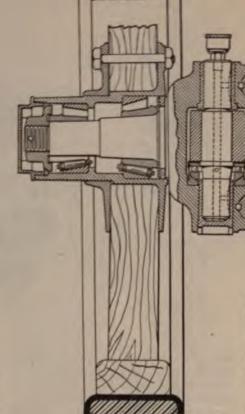

The front wheels are equipped with 36x5 inch solid tires and 36x31/2 inch dual tires.

The chassis weighs 4,500 pounds and with the motor running at 800 r. p. m. the car runs at the following speeds: High gear, 9 miles per hour; intermediate, 6 miles per hour; slow, 3 miles per hour; reverse, 21/2 miles per hour.

The metric system is used on all shop drawings for automobiles by the American Locomotive Company, except where the English system is necessary to accommodate the use of standard parts.

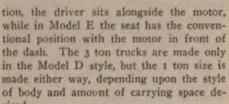

# Wilcox Motor Trucks.

The H. E. Wilcox Motor Car Company, Minneapolis, Minn., are building a line of commercial vehicles in 1 ton and 3 ton sizes, and in two models, characterized by the position of the driver relatively to the motor. In Model D, shown in the illustra-

sired.

The four cylinder motor for both the 1 ton and 3 ton cars is of 41/4 inch bore by 41/2 inch stroke, with cylinders cast in pairs and valves on one side. The cylinders are offset from the vertical centre line of the crank shaft and are cast from air furnace iron, as are the pistons. Oiling is by splash, the proper oil level in the crank case being maintained by a pump drawing from a

WILCOX THREE TON TRUCK, MODEL D.

chamber cast in the lower part of the case. the excess oil returning through an overflow. The system, as worked out in its details, insures an even distribution of oil regardless of the inclination due to grades. The regular ignition equipment consists of a Bosch high tension magneto, with storage battery and coil,

FRONT AXLE END OF ALCO TRUCK.

THE RUSSILESS ASE

The same three speed gear box is used on all models, with twenty-one and fortyeight tooth bevel gears and twelve and forty-five tooth sprockets on the 3 ton, and twenty-three and forty-eight tooth bevels with fourteen and forty-five tooth sprockets on the I ton truck. With these gear ratios the 3 ton truck will run 15 miles per hour, and while only 18 miles per hour is claimed for the I ton, it is said to be capable of dong 23.

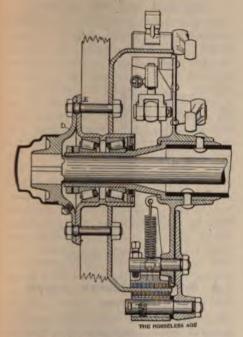

The 3 ton truck with open stake body weighs 5,600 pounds. The 1 ton Model D. with open stake body, weighs 4,300 pounds, and the I ton Model E, with the same body, 4,200 pounds. These trucks are assembled from standard parts.

# Timken 1910 Rear Axles.

The Timken-Detroit Axle Company are manufacturing two sizes of rear axles for the coming season. The smaller axle is for cars up to 35 horse power and about 2,400 pounds in weight, while the larger axie is recommended for machines up to 60 horse power and weighing 3,200 pounds. The two axles are nearly alike, except for size, and will be described together.

Following advanced practice the housing for the axle shafts and gears is in one piece of pressed steel, of the shape shown by the illustrations. It is formed from upper and lower halves of three-sixteenth inch stock, which extend from wheel to wheel, autogeneously welded together on the horizontal plane. This brings the weld practically in the neutral plane, and the completed housing forms a truss whose strength is far in excess of that required. External truss rods are done away with.

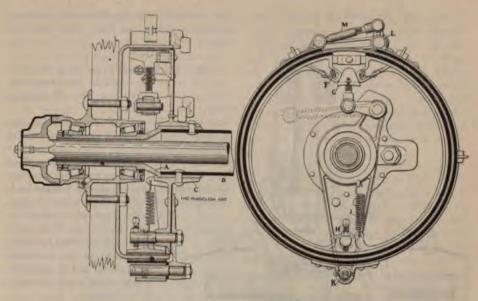

The section of the central assembly shows

END ASSEMBLY OF SMALL AXLE.

the driving mechanism of the larger axle, but that of the smaller is practically the same. It will be seen that driving gears are carried in a cast unit, so that all the driving strains are taken by this casting. This unit is assembled on the bench, the bevels being accurately meshed, and is then slipped in place through the large hole in the front of the pressed steel housing. It is fastened in correct position by numerous bolts.

The large opening at the rear of the housing is closed by a thin pressed steel cover held by cap screws secured by lock washers. This opening makes the parts very accessible. The axle shafts have square ends which fit into the differential gears. They may be withdrawn through the outer ends of the axle tube. When they are drawn out far enough to clear the differential bearings the driving bevel and differential may be removed from the rear by taking off the

END ASSEMBLY OF LARGE AXLE.

caps to the seats for the differential bearings. The pinion and shaft may then be removed through the rear opening.

The short Timken bearings are used throughout. Those to the differential are adjustable by collar nuts. The mesh of the gears may be varied by this adjustment and by the nut which contains the cup of the bearing at the rear of the pinion. This latter is adjusted and locked through an opening just above it. The pinion shaft bearings are large and are placed a good distance

The sectional assembly of the end of the large axle shows a typical floating construction with the usual form of clutch hub. All parts are securely locked and working parts are protected from the dust. The sleeve A, which carries the wheel bearings, is machined from a forging, giving uniform metal, which is almost impossible to obtain when this reduced diameter is machined from the stamping. It is forced

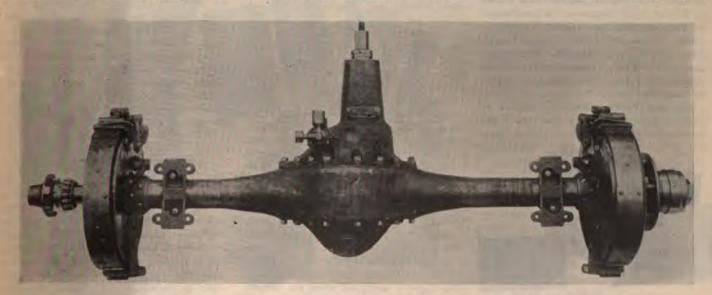

tightly on the end of the main housing B. Brake support C is placed over the two, and all three are fastened securely together by large rivets.

The end of the small axle is similar to that just described, except the method of driving the wheel. This is accomplished by forging D, which drives from the squared end of the axle shaft to bolts E.

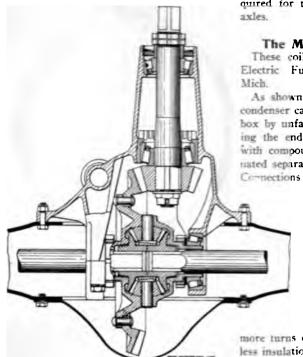

This size of axle is also made in a fixed hub or "non-floating" type.

The brakes for both axles are identical, except in size. Those for the small axle have an internal contact surface of 2x12 inches. For the large axle these dimensions are 2½x13½ inches. Both brakes are faced with asbestos copper fabric, and make contact their entire length.

The internal brake consists of a cast shoe expanded by wedge G. It is held central in the off position by springs F and J, which pull the shoe against two stops at the open ends and against adjustable stop I.

NATIONAL 1910 PRESSED STEEL REAR AXLE MADE BY TIMKEN-DETROIT AXLE COMPANY.

CENTRAL ASSEMBLY OF TIMKEN 1910 AXLE.

These stops also hold the brake in the proper position sidewise, and, together with the springs, prevent rattling. Anchor H prevents the brake from turning.

The external brake is a simple spring steel band. The operating bell crank is pivoted in the end L and pulls adjustable link M to contract the band. This is about the simplest mechanism suitable for this purpose. The brake is held firmly in its off position by the spring of the band, and by the helical spring K located in a recess in the anchor pin. These force it tightly against stops, which hold it firmly, both radially and sidewise.

Spring seats are split and the ports held together with two bolts. This allows the axle to be readily detached from the springs. The torsion member is of the V or Renault type, hinged to the gear housing so as to swing horizontally.

Alloy steels are used in all important parts of these axles. Their quality is maintained uniform by an extensive physical and chemical laboratory whose tests insure careful heat treatment.

The new Timken factory at Detroit is equipped with the latest apparatus for forg-

ing, machining and assembling the parts required for these and their other types of axles.

# The Michigan Type A Coils.

These coils are made by the American Electric Fuse Company, of Muskegon, Mich.

As shown by the cut the secondary and condenser can be readily removed from the box by unfastening two clasps and removing the end piece. The box is not filled with compound, but the parts are impregnated separately before they are assembled.

metal plugs, which fit tightly in suitable metal sockets. This construction permits the parts to be inspected and tested, and if any part breaks down it can be readily replaced.

The coils are wound with American black enamelled wire. The secondary is wound in sections, allowing

more turns of wire in a given space, since less insulation is needed, owing to there being less difference of potential between adjacent wires. Danger of breakdown is also greatly reduced.

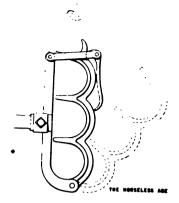

The American Company are also making a coil in a moisture-proof metal case. This is designed to bolt directly to the motor, which placing greatly simplifies the wiring.

The American Company are one of the only two makers of spark coils in this country who produce every part of their coils.

# The Bair Auto Top Holder.

The Auto Specialties Manufacturing Company, of 375 Golden Gate avenue, San Francisco, Cal., are marketing the Bair auto top holder, a device designed to keep the bows of an automobile top from rattling when the top is down. The holder consists of two bars hinged together, one of the bars being substantially straight and the other formed with semi-circular slots to fit the individual bows. The device is made to fit three, four or five bow tops. The free end of the straight bar is provided with a pair of shackles and a quick-operating spring clamp for rapidly placing and removing the holder.

None of the old style socket devices at present in use separate the weight of the bows, so that whenever there is jarring or jolting from crossing ruts or obstructions all the weight of the top comes down with a bang on the bottom bow. Straps always have the tendency to stretch in dry weather, permitting the bows to flap and jar, or to shrink in damp weather, so that frequently when the top must be raised in a hurry it becomes necessary to cut the straps. Where socket separators are used, the strap is also necessary to keep the bows together. and all the inconvenience incidental to a strap alone is increased when the strap is used as an adjunct to the socket separators.

BAIR AUTO TOP HOLDER.

# A British Automatic Speed Governor.

Vice Consul H. M. Byington, of Bristol, reports as follows concerning a new British apparatus which controls the speed of motor

According to the published description of a practical trial, the device automatically removes the clutch when the speed of the car slightly exceeds the arranged limit, and when necessary the brake is also automatically applied until the rate is reduced just below the limit. The brake is then quickly but gently removed and the clutch again put in. A semaphore is automatically raised to warn the driver when he is approaching the maximum. The mechanism, which fits in a compact aluminum box and works in oil, takes very little space. It is put in action or out of gear in an instant. and there is no need to stop or slow down the car while this is being done. The apparatus can be locked up so that the driver of a car cannot exceed the speed desired by the owner

Every effort was made on the trial to get the car to exceed the limit, which was set for 16 miles an hour. On coming to a fairly steep hill the engine was allowed ful power and the car instantly started to gain speed. But as soon as the limit was reached the brakes were applied strenuously, as if by magic (though no sudden jar was experienced), and the engine merely "raced" without the slightest effect on the car, the speed being maintained at the 16 mile rate throughout.

# Special Physician's Car.

The Buckeye Manufacturing Company, of Anderson, Ind., is preparing to build a car especially adapted to the use of physicians, it is reported. The design will be from ideas suggested by Dr. N. S. Wood, an Anderson physician. It will include the salient features of a runabout and ambulance, and will be designed for emergency work by physicians. A folding stretcher will be one of the special features.

# Franklin Die Cast Bearings.

The H. H. Franklin Manufacturing Company, of Syracuse, N. Y., who have been making die castings for the past fifteen years, have recently concentrated their attention on die cast hard babbitt bushings for gasoline and other engines. Perhaps one of the reasons for this recent move is that automobile motors, for instance, are now made by many manufacturers in such large numbers that the pro rata cost of the dies has become quite small, and in the case of the largest manufacturers the die cast bushing would be materially cheaper than a phosphor bronze bushing. It is, however, not so much the saving in cost as the superior bearing qualities of their hard babbitt composition that the Franklin Company lay the greatest stress upon. A bearing metal must have a low frictional coefficient, so as to minimize the loss of power in the bearings and their consequent heating, and it must also have sufficient rigidity to stand up under the pressure imposed upon it and not peel up, squeeze out, sliver or crush. The need for rigidity is especially imperative in the case of gasoline engine bearings, as not only is the unit pressure high but the pressure varies continuously between the maximum and zero. This condition at once eliminates the softer babbitts, which would not stand up in the work. There remains the choice between phosphor bronze bushes and hard babbitt die cast bushes. The Franklin Company claim that the hard babbitt bushing is superior in every respect. Its most valuable quality is the plasticity of the babbitt, which prevents cutting of the shaft in case the bearing should become heated owing to the accidental absence of oil. The rigidity of the bushings made by the Franklin Company's process is increased somewhat by the pressure to which the metal is subjected in pouring. These bushings have been used on one well known make of cars for the past six years, about 7,000 cars having been fitted with them, and are said to have given universal satisfaction.

In connection with the theory of bearing metals, it is held that in order to maintain a low degree of temperature under pressure and thrust the metal must have a plastic matrix for its body, combined with a network of small, compact crystals to carry the load and stiffen the casting. Zinc is still used by some for making this granular structure, but zinc offers no advantages, except in price, over the antimony and copper alloys, with tin forming the plastic body. All zinc-copper alloys are devoid of the plastic element. The same is true of nickel and aluminum. Such allovs used as a bearing are said to fail at high speed, their use being confined to large bearings under great pressure running at an even speed

The die casting process lends itself to the production of both split bushings for the crank pins and crank shaft main bearings, and for the cylindrical bushings for cam shafts and other auxiliary shafts of the engine and car. The split bushings are generally cast with their oil grooves and plugs for keeping them from turning in their boxes. In the "full" bushings it is necessary to cut the grooves afterward, however. The bushings are completely finished when cast, except for a slight trimming at the edges. Not the least advantage of these die cast bushings is their absolute interchangeability. The writer was told that if 500 bushings are made from the same dies the cost is about equal to that of phosphor bronze bushings; also that the die casting process is limited to bushings of less than 6 or 7 inches in diameter, which, of course, includes a large range of work.

FRANKLIN DIE CAST BEARING BUSHINGS.

# The Chicago Meeting of the S. A. E.

The midsummer meeting of the Society of Automobile Engineers was held in Chicago August 5 to 7, inclusive. Through the courtesy of F. J. Newman, chairman of the special committee of the meeting, the society was enabled to make the Illinois Club its headquarters during the meeting, and the privileges of the club were extended to all visiting members for a period of two weeks.

The first day of the meeting was given up to visiting the Algonquin Hill climb, machines for conveying the members to and from the town of Algonquin, a distance of 60 odd miles from Chicago, being furnished by the courtesy of various Chicago dealers.

On Friday the society assembled in the spacious banquet hall of the club to transact business and to listen to the reading of the papers presented. After business had been disposed of Professor Carpenter read a paper on the "Commercial Test of a Six Cylinder Pierce Water Cooled Motor." This paper was written as thesis work by J. A. Luhrman and G. W. Woodward under Professor Carpenter's supervision. Professor Carpenter did not confine himself to the published paper, but spoke on various practical points brought out in the tests, among which were some points on the use of the manograph. He also spoke of the use of a specially devised arc lamp and of various instrumental errors of the instrument and their causes. One point about the motor upon which he laid special stress was the high thermal efficiency of 20 per cent., which was as high as had ever been attained with anv internal combustion engine using gasoline as fuel.

Other papers read were by Dr. Sohal on "The Possible Increase in the Weight Efficiencies of Storage Batteries," and "Some Points in the Care and Operation of Vehicle Batteries," by H. H. Beck. The discussion of these papers was postponed until the Saturday session. During the afternoon about twenty of the members visited the Pullman works on a tour of inspection.

The final session was held on Saturday, August 7, at the South Side Country Club. the members being conveyed there in autos loaned by the Chicago dealers. The papers read at the previous meeting were first opened for discussion. The discussion on the two battery papers was quite interesting. Some facts were given by Mr. Churchward on weight efficiency of the later forms of Edison battery. The discussion of the Beck paper turned mostly on the comparative values of the hydrometer, voltmeter and ampere-hour meter as an aid to keeping batteries in condition and estimating the amount of charge still remaining in them. Then followed the reading of the papers "Energy Consumption of Commercial Vehicles," by Alexander Churchward; "Notes on Lubricating Oils," by F. H. Floyd, and "The Electric Cradle Dynamometer," by H. S. Baldwin.

The discussion of Mr. Churchward's pa-

per (which paper is reprinted elsewhere in this issue) brought out many interesting facts regarding the effect of tires of various kinds and conditions on the mileage, such as the degree of inflation of pneumatics and the composition of solid rubber tires. This discussion was largely among those members connected with firms having to do with electrics, and it would seem that much more thought had been given to these minor matters by them than by the makers of gasoline cars. As Mr. Baldwin was not present, there was no discussion of his paper, although Professor Carpenter made some remarks on dynamometers in general.

Two papers were laid over until the next meeting. At the close of the meeting the members and guests were invited to a lunch as the guests of the Woods Motor Vehicle Company. After the lunch quite a number of the members availed themselves of the club privileges. The attendance at both sessions was about forty, and was remarkble for the large number of members coming from a distance, probably more than half living at least 500 miles from Chicago.

# Manufacturers' Contest Association to Discuss Rules.

The general rules committee of the Manufacturers' Contest Association will hold a meeting at Indianapolis, Ind., August 19-21, during the initial races on the new Indianapolis Motor Speedway. Among the most important subjects to be discussed are the following:

- 1. Recommendations as to changes in the classifications and weights for 1910 season.
- 2. Changes to be recommended to the contest board for the American Automobile Association rules of 1010.
- 3. The possibility of the support by the Manufacturers' Contest Association of an impartial and thoroughly capable technical committee, which shall serve at all competitive contests.
- 4. The arrangement of a definite and logical schedule of all important contests for the season 1910, with a view to the announcement in September of this year of the approximate dates, character and general conditions governing all such events. (From information at hand it is a certainty that the promoters of all annual events will for 1910 be very glad to co-operate, as may be suggested by the M. C. A., in so scheduling these contests as to avoid interference of dates. The interests of the promoter and of the manufacturer who is asked to support the contest with entries are mutual.)
- 5. National events. How many shall be supported and of what character?
- 6. International events. How many shall be supported and of what character?
- 7. Endurance contests. Action to be taken upon the recommendation made by the National Association of Automobile Manufacturers, that only one endurance contest be scheduled for any one section of the country, and not more than four be supported by manufacturers' entries.
- 8. Road racing versus track events upon specially constructed speedways of any less than two miles in circummerence.
- 9. Shall racing upon existing mile and half mile horse tracks be countenanced or supported in any way?
- 10. A standard electrical timing device for the elimination of human error in the timing of all important speed events.
- 11. A satisfactory definition of the term "stock car."
  - Steps to insure the enforcement of the rule ag the character of the publicity matter

employed by any maker covering the performance of his cars in any contests. All such publicity must be in accordance with the facts.

13. A formula for the proper comparison of the performances of steam and gasoline automobile motors

# Registrations by Makes in Minnesota.

According to recent statistics regarding the makes of cars registered in the State of Minnesota during the past year the Ford leads with 157, and others follow in the following order: Buick, 131; Cadillac, 105; Oldsmobile, 77; Maxwell, 64; Packard. 61; Overland, 55; Stoddard-Dayton, 50; Stevens-Duryea, 49; Mitchell, 45; Wilcox, 45; White, 41; Franklin, 41; Kissel, 36; Peerless, 29; Autocar, 27; Rambler, 27; Columbus, 22; Elmore, 21; Reo, 21; Aerocar, 20; Queen, 20, etc. That twenty Queen cars were registered shows that a great many of the registrations are of second hand cars, as this make has been off the market for over a year.

# Settlement Proposed in Royal-Duerr Dispute.

The Royal Tourist Car Company, of Cleveland, Ohio, and the receiver for its former New York agent (C. A. Duerr & Co.) have been in controversy for some time, the receiver making a claim of \$9,800, which sum was deposited by Duerr & Co. with the Royal Tourist Car Company, and the latter company make a counter claim for \$9,800 for damages and merchandise delivered. The Royal Tourist Car Company now offer to settle the matter by a payment of \$1,500, and a hearing on this proposal will be given at 2 Rector street, New York city, on August 19, at 11 o'clock a. m.

# New Auto Cylinder Plant.

The Frontier Iron Works, of Buffalo, N. Y., recently started a new iron foundry on Grant street, which will give employment to about 200 men. The company will eventually have six fireproof, reinforced concrete and brick buildings, and devote its chief attention to automobile cylinders. The officers of the company are Walter F. Semon, president; J. W. Semon, vice president, and James W. Murphy, secretary. The old plant of the company is located at the foot of Auburn avenue.

# Automobiles on Milwaukee Assessment Lists.

The tax commissioner of Milwaukee, Wis., announces that there are 1,081 motor cars on the tax rolls of the city, as against 491 in 1908. The value is \$634,860, against \$250,350 in 1908. As is natural, these figures do not show the real number nor the real value of cars in Milwaukee. It is interesting to note that the number of horse drawn vehicles of all kinds has decreased more than 10 per cent. The number of horses has decreased proportionately.

# To Manufacture Cars in Atlanta.

The White Star Automobile Company has taken up the manufacture of automobiles in Atlanta, Ga. The company at first built ' a high wheel machine, but discarded this design in favor of a touring car of modern appearance. It was incorporated with a capital stock of \$150,000, and is at present occupying part of the plant of the Atlanta Buggy Company on Means street. The first touring car was completed about two weeks ago. The 1910 models of the company will be exhibited at the Atlanta automobile show next November, and it is stated that they will also be entered in the endurance contests which are to be held in connection with the show. The car is a five passenger touring car of 35-40 horse power, and is obviously of the assembled type. It has a four cylinder, water cooled motor, with 41/2x5 inch cylinders, a selective type change gear and a shaft drive. Cars will range in price from \$1,250 to \$1,500, according to finish. Clarence Houston is president of the company and Larry Fell superintendent.

# General Motors Company Secures Option on Rapid Motor Vehicle Stock.

Following the recent announcement that W. C. Durant, of the General Motors Company, had purchased \$200,000 of the stock of the Rapid Motor Vehicle Company, there comes an apparently well authenticated report from Pontiac that General Motors representatives have obtained options on nearly all the remaining stock. There appears to be little doubt but what the options will be taken up at once. The present company recently started an addition, 100x640 feet, and three stories in height. It is reported that the General Motors, if they obtain control, will start a second addition, 100x300 feet, two stories in height, and also will erect a new building for woodworking and a new power plant.

# Alleged Ditching of Cars by Farmers.

Mayor Arnett, of Kokomo, Ind., is investigating a charge that Chief of Police A. M. Jackson, of that city, advised farmers to ditch automobiles that violate the speed laws. Several cars in the vicinity of Kokomo have been ditched recently by rails placed in the roads. Among those who have met with such obstructions are Edgar Apperson and Herbert Lytle.

# Garage Fire.

The garage of H. C. Bradley, of Fort Collins, Col., was destroyed by fire on July 30, causing a loss of about \$10,000. The fire is said to have been caused by a boy filling the gasoline tank of a car, spilling some of the gasoline onto a hot engine, thus igniting it. The boy was seriously burned about the face and head. Several touring cars stored in the garage were either destroyed or damaged.

# Commercial Applications.

# A Central Ohio Motor Passenger Service.

By E. Z. HAYS.

About the 1st of last March a joint stock company was organized at Warsaw, Ohio, under the name of "The Valley Auto Company," for the transportation of passengers and small packages. The chief object was and is the carrying of passengers up and down the Walhonding Valley, from Walhonding, through Nellie and Warsaw, to Coshocton, the county seat, a distance of about 20 miles. However, on putting our car in service, about the 1st of May, we found the demand for service so great that it was necessary to cut off a part of the proposed route, so that Walhonding, the proposed starting point, with about 7 miles of road is left out, and probably will be until we put on a second car, as we contemplate doing, should the present venture prove reasonably profitable.

We have been making two round trips per day, when we could run, but the unusually wet weather last spring was very much against us, especially in May and June. One of the road supervisors on our line, apparently to gratify a personal grievance against members of our company, does not work the road where needed, and, besides, there is still considerable ill feeling on the part of some citizens toward automobiles in general, mainly because their horses scare at them. Horses do not, as a rule, seem to like any size or kind of self propelled machine, but they are gradually growing accustomed to them, and the time is not far distant when they will not mind them at all. The fact is the automobile is here to stay, both as a private and a public conveyance, and the horse owners must put up with it. We have one citizen, a man who has been in the Legislature and held other important offices of trust, who swore autos should not be permitted to run on any road of less than 60 feet width. The auto people will have to bear with such overconservative characters until the public passenger automobile shall have demonstrated its practicability and its great convenience, and shall have become popular and virtually indispensable, as it will in the near future. Then the man who sings from policy will sing its praise.

### ROAD CONDITIONS.

But in this State the era of the automobile is not come, save in some limited sections where the people have improved their public highways. Our State laws are not stringent enough, not broad enough.

The road over which we run is built on Adam's plan and not McAdam's, except in patches where the river gravel has been utilized. While this is one of the most important roads in the county (Coshocton), it has been badly neglected, and much of the

work that has been done on it has not been applied in an intelligent manner. Nature has furnished an abundance of first class material for making a good road at a minimum of cost, but that material, which in no place along the line lies more than a quarter of a mile away, has been used but sparingly. The road grader, an excellent machine for road making, when judiciously employed, is the chief reliance of supervisors, as our road masters are called, and they depend on it to the exclusion, almost, of all other means. They hitch four to six horses to one of those machines, mount three or four men upon it and proceed to spoil miles on miles of good roads; requiring no work, by grading up from both sides, windrowing the sods and stones into the centre, where they remain to impede the passage of all kinds of vehicles, automobiles in particular.

We believe we will cover the 13½ miles of our route in an hour when the roads become settled and worn smooth, but one and a half hour per trip is about as good as we can do. Our route leads through a beautiful and interesting section along the Walhonding River, a very pretty stream, and is level, except for a couple of bad banks, needlessly taken in by the locators, probably for the sake of diversity.

#### CHARGES FOR EVERY SERVICE.

Our car has a capacity of sixteen passengers, though the public sometimes force us to carry twenty to twenty-four. The reader can imagine how snugly these must be packed-something like sardines in a box. Freight can be carried only in a boxlike rack hung onto the end of the car, and this necessarily limits the size and weight of packages. In this regard we find that much is expected of us in the way of unremunerative accommodations. "Well, you are coming up anyway, you run the car just the same, and you can do this for me, just as a personal favor," is an idea very prevalent. Our chauffeurs could find considerable employment in such odd jobs as exchanging shoes and corsets, in paying taxes and grocers' bills and in conveying verbal messages of the "I've not time before you start" kind. We have found it advisable to establish rates for all such chores. We have no charge less than 10 cents, which is for a package weighing not to exceed 6 pounds; 15 cents for 6 pounds, and all over 6 pounds I cent per pound, with some discretion left with the chauffeur as to bulky packages. Our passenger fare is about 3 cents per mile, but as we do not divide a five cent piece it runs sometimes over, sometimes under, this figure. The line is divided into 5 cent sections.

# PARALLELS RAILROAD.

We parallel the T., W. V. & O. Railroad from start to finish, but that road can hardly be said to be a competitor. Its passenger service is so unsatisfactory that we did not count the railroad as a factor against us when contemplating the organization of our company. From this point to Coshocton, the county seat, our fare is 30

cents; that of the railway is 20 cents, yet we have been carrying, when able to run at all, practically all the local pasengers, unless, owing to some attraction in the city, the requirements for accommodation exceed our capacity.

We take the same route back and forth, passing over the same bumps in the road and plunging through the same mud holes. By that means we become rather used to the peculiarities of our route, and these impediments are like old acquaintances.

There seems to be no good rule by which to calculate the value of prospective trips. One can never make a good guess whether a good load east means a good load west, or whether the noon or second trip will be made with a lighter or better load than that of the morning.

# GOOD ROADS MOST IMPORTANT.

Returning to the matter of roads, I wish to add some other thoughts. The good roads question is the one of first importance with those who are contemplating becoming owners of automobile lines for passenger and freight carrying. In this State considerable legislation has been enacted, but it has not been productive of better roads to any extent. One reason for the failure is to be found in the fact that no one is held responsible, either criminally or financially, for damages to vehicles directly chargeable to the conditions of the public highways. Officers having the roads in charge, township districts and counties should be held amenable, if they fail to make repairs after notice of the dangerous condition of any road, and any citizen should have authority to serve such notice in his individual name. Politics cuts some figure. The office of supervisor has in years past, and is now, looked on as one of no great importance, and is used as a crumb to be thrown to some of the small fry district and township politicians to hold them in line and keep them "up on the bit."

### ROAD MAINTENANCE.

The supervisors of roads should be men employed by the year to go over the roads of a certain district and put in their time each day filling small damp or wet spots before they become large mud holes, and leading the water from the roads. They should have two horses and a wagon and be well equipped with all necessary tools. Two days' labor should be represented by cash in the district treasury, and no man (or woman) should be allowed to vote who has not paid poll tax for road purposes. The supervisor should have authority to conscript men and teams for road work, for which he should pay cash at the prevailing prices. He should work out the taxes assessed, seasonably and judiciously. He should be under the control of some township or county officers, who, with the supervisor, should be liable, after notice, to parties injured in property or person because of the bad condition of roads or bridges. He, the supervisor, should be of good judgment, with no enemies to punish or friends to favor. He should be a good,

honest, independent gentleman, not a rude, arrogant, blustering bore, as is too often the case

All owners of automobiles should be active members of good roads organizations, and should keep the cause constantly before the public eye. Members of the Legislature, or, rather, candidates for the Legislature, who will not work and vote for good laws to make good roads should be permitted to pass by on the other side election day.

#### ORGANIZATION OF THE SERVICE.

Our company is known as the Valley Auto Company, Incorporated, and the officers are as follows: J. P. Darling, Nellie, Ohio, president; W. W. Frederick, Warsaw, Ohio, vice president; E. Z. Hays, Warsaw, Ohio, secretary, and E. M. Wright, Warsaw, treasurer.

We make two round trips daily, except when some attraction at the county seat demands more service, in which case we add a trip. We run 54 miles daily, the maximum speed being a mile in four minutes; we average about nine passengers per trip. The chauffeur and gasoline are the chief items of expense. Solid round tires, 41/2 inches in width, are used. We consume 2 to 3 gallons of gasoline per trip, and I gallon of oil. There was no public conveyance over our route before we put the auto on. We store our vehicle in a large shed, and have a man employed to go over it daily to tighten nuts, etc. Our driver was sent to the shop for a couple of weeks for instructions before we began running. We have a second man who got his training on the car from the first man. We do not insure, although we contemplate doing so. We have a guarantee for one year.

# Delivery Contract Service for New York.

The Motor Delivery Company, with offices at 141 East Twenty-fifth street, New York, and a garage at 3-5 Lawrence street, near 126th street, who were awarded the mail collection and transportation contract on Route 407,021, New York city, for four years at \$44,826 per year, also conduct a mercantile delivery service, furnishing cars on a yearly contract, with the distinctive bodies, painting and advertising desired by the merchant leasing them. Complete maintenance of the cars is assumed by the Motor Delivery Company, who also furnish the driver, but the merchant provides a man or boy to handle the goods. For this service the prices, on a year's contract, are as follows:

1,000 pound delivery	\$10.00	рег	day
2,000 pound delivery	11.00	per	day
2 ton truck	12.00	per	day
3½ ton truck	13.50	per	day
5 ton truck	15.00	per	day

In addition to these two lines of work a general garage business will be done, provisions being made for the handling of gasoline as well as electric cars. The president of the company, C. H. Bardwell, has

had an extensive experience in the handling of city and suburban express work, having been connected in an executive capacity with the Metropolitan, United States, American and National Express companies.

#### Commercial Notes.

It is reported that motor vehicles will shortly be put in service for the collection of the mails in Chicago.

The Post Office Department has leased a Brush car for use in mail collection and delivery in Atlantic City, N. J.

The Nashville Taxicab Company, of Nashville, Tenn., put three more Sultan cabs in service on August 4, and expect to add three more additional ones before the end of the month.

C. B. Saxby, a Hancock, Mich., liveryman, has opened a motor livery business in Hancock and Houghton, Mich., with two Franklin cars. One of the cars is to be stationed at the Douglas House, in Houghton.

Albert Shoaf, a rural mail carrier out of Petersburg, Ind., has purchased an automobile which he will use in delivering mail in the future. He figures that by using an automobile he can have about three-fourths of the day to devote to other interests. His route is 25 miles long.

The R. L. Morgan Company, of Worcester, Mass., are reported to have secured a contract for 100 trucks from the American South African Commerce Company, of Johannesburg, South Africa. The contract involves the sum of \$350,000. The trucks are to be used in connection with the mines of the company.

According to a report recently received by the Indianapolis post office, which on July I increased its automobile delivery and collection equipment from two to three automobiles, the vehicles are covering between 52 and 64 miles a day, and it is estimated that each of them is doing three times the work done by a horse wagon

It is planned to establish an automobile bus line between one of the traction terminals in Washington, D. C., and the heart of Rock Creek. Samuel Gassenheimer has applied to the District Commissioners for a permit. He proposes to run six cars, seating thirty to forty passengers each, and to charge to cents fare, with stop-over privileges at any point along the route.

The board of public safety, Indianapolis, is inviting demonstrations of motor fire apparatus, Fire Chief C. E. Coots having recommended that such apparatus be purchased. There is no appropriation for the purchase of such vehicles this year, but should demonstrations prove successful provision will be made in the annual budget for 1910 which will be sent to the city council within a few weeks.

Practically all ambulance work in Indianapolis is now being done by gasoline cars, which have proved practical for the purpose. The Indianapolis City Dispensary, Flanner & Buchanan and the A. M. Rags-

dale Company are those who have recently purchased such vehicles. The latter's car resembles a limousine, and has not the outward appearance of an ambulance. It is reported that the city will purchase an ambulance for the City Hospital.

R. J. Hofner & Co., furniture dealers, have opened a private garage at 104 West Thirtieth street, New York city, for their gasoline trucks.

# Tire Manufacturers Ask for Investigation of Illegal Combine Charges.

A Buffalo, N. Y., paper some time ago printed an article in which it was charged that a tire trust existed which could boost the prices of automobile tires at will, and in which an investigation of the alleged trust was demanded. Meanwhile seven of the largest tire companies in the country, viz., the B. F. Goodrich Company, of Akron, Ohio; the Hartford Rubber Works Company, of Hartford, Com; the Diamond Rubber Company, of Akron, Ohio; the G & J Tire Company, of Indianapolis, Ind.; the Fisk Rubber Company, of Chicopee Falls, Mass.; the Goodyear Tire and Rubber Company, of Akron. Ohio, and Morgan & Wright, of Detroit. Mich., have secured Job B. Hedges, of New York, as attorney, and requested United States Attorney General Wickersham to make an investigation of the charges. Attorney General Wickersham has instructed District Attorney O'Brian, at Buffalo, to immediately proceed with the investigation. In his letter to the Attorney General Mr. Hedges declared that if it was merely a question of any individual manufacturer being libeled by a newspaper, he could have recourse to ordinary procedure under State laws, but this was a case of damage to a whole trade, involving interstate relationship and violating national laws, hence the appeal to the National Government. If a conspiracy in restraint of trade did exist, he said, it clearly was the duty of the Attorney General to prosecute the manufacturers. If one did not exist then it became equally the duty of the Government to protect when public accusations had been made. The tire makers claim that they have no illegal combination, and if the charges cannot be substantiated a libel suit will probably be instituted against the publication making them. Who was behind the charges which were made in the Buffalo Courier of July 15 has not yet become known. The Buffalo A. C. has repeatedly been mentioned in this connection in the Buffalo papers, and it has also been asserted that a co-operative buying league with headquarters at Buffalo, which could not get the tire manufacturers to accede to its demands, had something to do with the case. The developments in the case will be awaited with interest by the trade.

# MINOR MENTION

The Economy Motor Car Company, of Joliet, Ill., has recently completed a light delivery wagon.

The Hercules Electric and Manufacturing Company, Indianapolis, Ind., are building an addition to their plant,

The Jackson Wheel Company, of Chicago, Ill., who plan to manufacture a spring wheel for automobiles, may locate in Waukegan, Ill.

The B. F. Goodrich Company Detroit branch has recently been moved from 266 Jefferson avenue to a new building at the corner of Woodward avenue and Garfield street.

H. E. Wilcox, of the Wilcox Motor Car Company, Minneapolis, Minn., recently visited Detroit, where he placed orders for the engines and other parts for the company's 1010 output.

A new company is being organized in Portland, Ore., for handling the White steam and gasoline cars. C. A. Eastman, of the San Francisco White branch, is at present in Portland.

The receiver for the Oscar Lear Automobile Company, Springfield, Ohio, has taken out a building permit for a \$1,500 addition to the plant. The company will install new machinery at a cost of \$7,500.

The Fiat Automobile Company, who have decided to locate in Poughkeepsie, N. Y., are soliciting bids on a large line of machine tools, including lathes, drill presses, milling machines, gear cutters, grinders, etc.

F. W. White, a negro rural mail carrier on rural Route No. 1, out of Argenta, Kan. has purchased a second hand motor buggy for use in covering his route. He has a route 28 miles long and delivers mail to 1.600 families.

Ralph Rogers, of Chicago, has constructed an automobile of the high wheel solid rubber tire type, and is in correspondence with F. E. Eagan, secretary of the Commercial Exchange of Burlington, la, regarding a plan to manufacture the car in that city.

An interurban automobile road of 2x6 inch timbers is to be laid down between Carrizo Springs and Asherton, Tex., according to report. The road is to be used for both freight and passenger haulage by automobiles, and is designed as a feeder for the Asherton road.

The business men of Rockford, Ill., are said to be of the opinion that an automobile factory would be of much value to the city, inasmuch as the skilled labor employed in automobile construction is well paid for. Many cars are being bought in Rockford, and it is thought if a machine was manufactured there it would be patronized by local buyers. It is not unlikely that an

effort will be made to organize a manufacturing company among local capitalists.

The Auto Parts Manufacturing Company, Muncie, Ind., are enlarging their plant.

The County Board of Minneapolis, Minn., has decided to purchase an automobile for the use of the county officials.

The Rider-Lewis Motor Car Company are just moving into their new factory at Anderson, Ind., and expect to be in running order early in the fall.

The Muncie Motor Truck Company, Muncie, Ind., are planning to build 500 trucks of a ton and ton and a half capaity. H. L. Warner is chief engineer.

The Wadhams Oil and Grease Company, of Milwaukee, Wis., has taken up the sale of Wallman pressed steel gasoline storage tank, which is placed underground, with a tube brass pump above.

It is reported that the Jonz Automobile Company, of Beatrice, Neb., will shortly be reorganized with increased capital. Besides the Jonz automobile a number of specialties are to be manufactured.

A new firm has been organized at Du-Bois, Pa., to manufacture agricultural machinery propelled by gasoline motors, and will also finish a number of automobiles left uncompleted by its predecessor.

The Roman Automobile Company, Philadelphia, Pa., have leased the property at 238-240 North Broad street for a term of years, at a rental of \$6,000 for the first year and an annual increase thereafter.

The Courier Car Company, which was recently organized by members of the Dayton Motor Car Company, in Dayton, Ohio, began work in the former plant of the Kinsey Manufacturing Company, on Wayne avenue, on August 2.

The Superior (Wis.) Iron Works are manufacturing a new gasoline traction plow invented by Robert Russell, of Stevens, Minn. The tractor has covered 10 acres a day in the tests. The Superior Works manufacture the entire machine.

The Police Department of Saginaw, Mich., has recently been provided with a motor patrol, and the city council has now decided to erect a brick garage of ample dimensions for housing the vehicle alongside of the police department building. An appropriation of \$2,000 has been made for the erection of the garage.

The Northern Pacific Railroad is having 250 cars built specially for the transportation of automobiles. Each car is designed to carry two autos. The cars are 41 feet long, 8 feet 6 inches wide and 10 feet 8 inches high. The doors on opposite sides of the cars are staggered so as to facilitate the loading and unloading of the vehicles.

The Crow Motor Car Company, Elkhart, Ind., has secured a three years' lease for the factory building at the southeast corner of North Main and Simonton streets from August 1. The building is a two-story brick structure, 60x300 feet, and was at one time occupied by the Soudan Bicycle Company. The incorporators of the Crow

Motor Car Company are Dr. E. C. Crow, M. E. Crow, and F. A. Howe.

The cars turned out by the Interstate Automobile Company, of Anderson, Ind., for the 1910 season will be fitted with the U & H master magneto as regular equipment.

The Speed Changing Pulley Company, Anderson, Ind., will confine their efforts this season to a \$650 car, with a two cylinder opposed water cooled motor, shaft drive and rumble seat, of which they expect to make 3,000.

The Illinois Automobile and Parts Company, Main and Globe streets, Peoria, Ill., will add an addition to their plant that will double their present capacity. The new building will be used as a display and sales-room and a storage warehouse.

The Standard Leather Company, of Pittsburg, Pa., which has recently passed under the control of William J. Harvey and George J. Lappe will in the future cater specially to the automobile trade. The company was organized in 1840 and has a capital stock of \$400,000.

The E-M-F Company, Detroit, Mich., has taken out a building permit for two new buildings to cost \$75,000. One will be a three story building 460x56 feet, to cost \$50,000, and the other 240x60, to cost \$25,000. The new buildings will be located between Clark and Scotten avenues.

W. E. Dudley, Grand Rapids, Mich., has established a sightseeing service with a three seated car, accommodating twelve to fifteen passengers, and makes a round trip through the parks and to points of interest in the city every two hours. He makes his headquarters at the S. A. Dwight garage.

The Wordingham Manufacturing Company, recently incorporated in Milwaukee, Wis., to manufacture foot horns and motor car specialties, are working on a new signal device on the lines of the talking machine. It is a steel disc and recorder attachment for the regular horns and is expected to pronounce entire sentences.

It is reported that the General Motors Company, on July 29, paid \$4,500,000 in cash to the stockholders of the Cadillac Motor Car Company, for the purchase of the company's business. Had the money not been paid before August 1, it is said that another dividend of \$150,000 would have been paid to the Cadillac stockholders.

At the conclusion of the recent meeting of vehicle manufacturers in Chicago it was announced that an increase of 10 per cent. in prices has been decided upon. In explanation of the move it was said that the prices of raw material had gone up and automobile manufacturers had drawn workmen away from carriage making by offering higher wages.

The Minneapolis (Minn.) Motor Drivers' Club has been incorporated and is endeavoring to secure a clubhouse. Both drivers and repair men will be admitted to membership, but two years' actual experience in either line of work is one of the conditions of admission. F. A. Ost is presi-

dent, Chris. Owens vice president, Matthew Miles second vice president, Oscar Hall secretary and George Gagney treasurer.

J. B. Miller, of Perham, Minn., has purchased a touring car for use in his livery. J. P. Larigue has designed a light delivery car with friction drive, to sell at \$1,000. It will be made by a concern in Chicago

well known as bicycle manufacturers. The Velie Motor Vehicle Company, Moline, Ill., have increased their capital stock from \$150,000 to \$250,000. The 1910 models of the company will be announced shortly. and it is said to be the intention of the company to turn out no less than 2,000 cars for the season of 1910.

The Motor Supplies Company has been organized in Philadelphia with Harry A. Housman as president and V. McC. Fulton as manager. The company will open offices and salesrooms on North Broad street. Mr. Fulton, the manager, is well known in Philadelphia trade circles, having been connected with the Foss-Hughes Motor Car Company and the Penn Automobile Supply Company for several years past.

# Club Notes.

An automobile club is being organized in Sterling, Ill. More than fifty car owners in the city have signed an agreement to join. An organizing meeting is to be called for at an early date.

An automobile club has been organized in Hannibal, Mo. The following officers were elected at the recent organizing meeting: Judge T. L. Anderson, president; Walter Logan, secretary.

The Rhode Island A. C., Providence, R. I., has made arrangements with the Narragansett Hotel garage on Dorrance street for the accommodation of club members who wish to leave their cars under cover. Club members may store their cars free in the garage at any time except between midnight and 7:30 a. m. Formerly the club had a station at the Rhode Island Motor Car Company garage at 69 Broad street

# New Building for Studebaker Philadelphia Branch.

The Studebaker Brothers Company of Indianapolis has been incorporated with the Secretary of State of Indiana to handle Studebaker-Garford, Studebaker E-M-F and Studebaker - Flanders cars. Temporary quarters have been secured at 214 West Vermont street, but a new building is at present being erected on Pennsylvania and New York streets to which the business will be moved about November 1. The building will have a frontage of 92 feet on Pennsylvania street and extend the full length of the block back to Susquehanna street. The following officers have been elected by the new company: Frederick Fish, president; Frank Staley, vice prestreasurer and general manager.

# Dealer to Market Car Under His Own Name.

The H. J. Koehler Company, of New York and Newark, N. J., whose New York office and salesroom is located at 1709 Broadway, will for the season of 1910 handle the Rider-Lewis and Hupmobile, and will also market their own car, known as the Koehler "40," which will sell at \$1,650.

# Death of Colonel Pope.

Col. Albert A. Pope, head of the Pope Manufacturing Company, of Hartford, Conn., and well known throughout the country as a pioneer bicycle manufacturer and good roads advocate, died at his summer home, Cohasset, Mass., on August 10. Colonel Pope had been in ill health ever since the collapse of the bicycle industry, and since July 9 last his condition had been serious, and his death had been expected. A short biography of Colonel Pope will appear in our next week's issue.

# Opening of Indianapolis Speedway.

It is understood that the five mile course of the Indianapolis Motor Speedway will be finished in ample time for the meet of the American Federation of Motorcyclists to be held on August 13 and 14. About 100,000 cubic yards of stone has been used on the course, together with about fifty carloads of pitch. The stone has been furnished by eighteen different concerns, no one plant being large enough to supply the stone as fast as needed.

# Allyne's New Foundry in Detroit.

An addition will shortly be made to the Detroit automobile and parts factories located on the Boulevard, the Allyne Brass Foundry Company having just purchased a site on Chene street, just north of the Detroit Steel Products Company. This site contains about 24 acres. It has a frontage of 498 feet and is 2,105 feet deep. The first buildings will probably be 350x350 feet, and will be equipped to handle about 36 tons of aluminum a day. The old plant on Bellevue avenue will be operated for a while as a brass foundry.

### Ford to Establish Branch Factory in Kansas City.

It is stated that the Ford agency in Kansas City, under the management of C. C. Meade, has done nearly a million dollar business during the past year. With an eye to future extensions in this territory the Ford Company has recently purchased from the George T. Moore Realty Company 31/2 acres of ground in Centropolis. This property is on Winchester avenue between Eleventh and Twelfth streets and just north of the Webster Gas and Gasoline Engine Works. It is understood that a one-story building of reinforced concrete will be erected at once, and that it will be used for assembling purposes. The building will be made heavy enough to carry additional stories.

### New Incorporations.

The Uptown Garage, Yonkers, N. Y .- Capital stock, \$2,000.

The National Motor Supply Co., Cleveland, Ohio.—Capital stock, \$10,000; F. M. Chandler, manager.

Lemey-Mills Auto Co., San Antonio, Tex-Capital stock, \$20,000. Fred H. Lemly, G. C. Mills and J. H. Gibson.

Caroline Automobile Co., Charlotte, N. C .- Canital, \$30,000. Incorporators, E. A. Robbins, O. A. Robbins and E. M. Bell.

Carolina Auto Co., Charlotte, N. C.—Capital stock, \$30,000. Incorporators, O. A. Robbins, E. N. Bell and E. A. Robbins.

Ogden-Farwell Garage, Milwaukee, Wis. ital stock, \$10,000. Incorporators, George F. Gerlach, J. M. Dorsey and A. C. Runkle.

Automobile Rim Securities Co., Brooklyn, New York.—Capital stock, \$150,000. Incorporators Harry Gargan and Paul G. Burroughs.

Ferris-Dunlap Motor Car Co., Dallas, Tex.—
Capital stock, \$10,000. Incorporators, Floyd A.
Ferris, O. E. Dunlap, Jr., and Neil White.
Keystone Auto Supply Co., Norristown, Pa.—
Capital stock, \$15,000. Incorporators, James S.
Boyd, John P. Leonard and Donald Stroud.

The Superior Motor and Machine Works, Superior, Wis.—Capital stock, \$15,000. Incorporators, Solon L. Perrin, H. J. O'Brien and H. C. Lavery. G. J. G. Motor Car Co., White Plains, N. Y.

—Capital stock, \$5,000. Incorporators, Mortimer M. Grossman, George Grossman and Matilda

Rooklidge-Gilmer Co., Salt Lake City.—Capital, \$25,000. Incorporators, John W. Rooklidge, presdent and secretary; L. J. Gilmer, vice president and treasurer.

The Brown Auto Carriage Co., Cleveland, O. Capital stock, \$15,000. Incorporators, Brown, H. E. Benfield, C. C. Wise, I. R. Graham and R. A. Wilbur.

The Schreiber Motor Car Co., of Milwaukee, Wis. (State agents for the Locomobile and Knox).—Capital stock, \$25,000. Incorporators, Herman F. Freidner, Robert G. Washold, John P. Foley and others.

The E. Z. Auto Go-Cart Co., of Beloit, Wis. has increased its capital stock from \$25,000 to \$50,000, and increased the number of directors from five to seven, by an amendment to its articles of incorporation.

The Instantaneous Lighter Co., Columbus, O.-A device which enables the driver to light all lamps from his seat. Capital stock, \$30,000. Incorporators, F. C. Bargar, president and secretary; Byron L. Bargar, treasurer; H. S. Barrett, director.

The Stearns Auto Livery Co., Milwaukee.— Capital stock, \$1,000. Incorporators, A. F. Eckstein, J. E. Moore and H. T. Eckstein. company is an auxiliary to the Wisconsin Auto Exchange, agents for the Stearns and other lines.

The Minneapolis Motor and Truck Co. has recently been incorporated with \$500,000 capital to manufacture commercial vehicles. A factory is to be erected at Ninth street and Ninth ave southeast. The incorporators include Frank Healy. Dr. W. B. Murray, Carl C. F. Budtz, Michael A. Gerber and H. H. Natwick. The first model turned out is a delivery car to sell at something less than \$1,000. It is provided with a platform body 9 feet 7 inches long and has a capacity of 1 ton. The engine is of the two cycle type and has three cylinders, and is rated at 25 horse power. It appears that the company will cater espe to the needs of the farmers. Trucks of large capacity, all equipped with three cylinder two cycle motors and shaft drive, will be brought out later.

# New Agencies.

Atlanta, Ga .- Tom Johnson, E-M-F. Sacramento, Cal.-Fred Kitt, Speedwell.

Vincennes, Ind .- Emison & Nicholson, Rambler. Tacoma, Wish., 751 Tacoma Avenue.-

tow, Palmer-Singer.

Jefferson, Wis.—Chas. F. Bullwinkel, Studenter. baker, E-M-F and Studebaker-Flanders lines.

# "Stables" Taken Over by Garage Firm.

The Imperial Motor Vehicle Company, New York city, have taken over the remaining one and half years' lease of the West End Stables of the building at 208-212 West Seventy-sixth street, and secured an extension of the lease to ten years. The Imperial Motor Vehicle Company have a capital stock of \$10,000. Harry Tonnell is president, G. W. Meade secretary and treasurer, Charles Bader vice president and F. C. Stinzing general manager. Mr. Stinzing formerly ran the Imperial Garage at 52-54 West Sixty-seventh street, the business of which will be transferred to the new company, and previously to that was connected with the Desberon Motor Car Company as designer.

The building is finely adapted to the purpose, having six floors and a basement, 75 feet by 92 feet 3 inches, with unobstructed light on three sides. Extensive alterations are being made, including the installation of steam heat on all floors, the boiler room in the basement being entered from the street only; cement floors in the first four stories, compressed air piped to all floors, a new elevator and electric lighting system using tungsten lamps. Storage for 1,100 gallons of gasoline is provided in a tank room at the rear of the building. The top floor will be used for painting and for the repair shop, in which will be installed a 32 inch lathe, a 13 inch metric lathe, a 24 inch drill press, a 12 inch drill press, shaper, power saw and forge, the latter being placed in a "lean-to" outside the building. It is expected to have everything ready for business by September 1.

# Wisconsin Auto Line.

The Appleton Auto Transfer Company has been organized at Appleton, Wis., with a capital stock of \$10,000, and the support of the Appleton Merchants' Association, to operate a passenger and baggage line ber tween Appleton and New London, Wis., via Black Creek, Shiocton, Hortonville and Stephensville. Two trucks, a twelve passenger and I ton truck, will be purchased. Two trips will be made each day, each truck starting at opposite points. M. D. Parmenter, secretary of the Merchants' Association, is manager.

# Imports and Exports for June.

During the month of June last there were imported 131 cars, valued at \$246,291, and parts valued at \$72,276, as compared with 71 cars, valued at \$153,521, and parts valued at \$61,927, during the same month the previous year. Of the cars imported last June 69 were from France, 44 from Italy, 9 from the United Kingdom, 6 from Germany and 3 from other countries. During the twelve months which ended with June, 1909, there were imported 1,624 cars, valued at \$2,905,-301, and parts valued at \$773,743, as compared with 1,045 cars, valued at \$2,500,134, ard parts valued at \$490,905, during the same period the previous year. The following table shows the valuation of our automobile imports during the past three Perry Hill from a standing start in 22 3-5 and Phillips Hill from a flying start in 28, giving him a total of 50 3-5. On Perry

# The Algonquin Hill Climb.

The second annual hill climb of the Chicago Motor Club on the Algonquin Hills, about 60 miles from Chicago, took place on Thursday last, August 5. Numerous classes were provided for in the program and the number of entries was quite satisfactory, while the attendance was larger than at any hill climb previously held in the vicinity. The event is peculiar in a way in that there are two hills, Perry Hill and Phillips Hill. The Perry Hill was climbed in the morning, from a standing start, and the Phillips Hill in the afternoon, with a flying start, and the times of each car for the two hills were added. The chief prize offered in connection with the event is the Algonquin Trophy, donated by the village of Algonquin, which is awarded each year to the driver who makes the best aggregate time for the two hills. Lew Lengle, of Allentown, Pa., was the winner this year, and will have his name inscribed on the trophy, below that of Frank W. Leland, last year's winner. Lengle drove a Chadwick car. He climbed

Hill the old record was 34 1-5 and on Phillips 29 2-5.

Following is a summary of the results: Class A, Division 6, \$150 and under-Maxwell

(Marshall), 1:47 1-5 total time. Class A, Division 5, \$851-\$1,250—Mason (Dusenberg), 1:13.

Class A, Division 4, \$1,251-\$2,000—Oakland (Bauer), 1:11 3-5. Class A, Division 3. \$2,001-\$3,000—Knox (Deni-

son), 1:03 3-5.

Class A, Division 2, \$3,001-\$4,000—Stoddard-Dayton (Englebeck), 0:59.

Class A, Division 1, \$4,001 and over-Thomas Six (Greiner), 1:15 2-5.

Class G, for electrics—Babcock (Peck), 1:21 1-5. Class I, Motor Buggies—Holsman (Renegar),

1:54 3-5. Class B, Division 5, 160 cubic inches and under— Buick (Burman), 1:25 3-5.

Class B, Division 4, 161-230 cubic inches-Velie (Stickney), 1:03 4-5.

Class B, Division 3, 231-300 cubic inches-Corbin (Bird), 1:03 4-5.

Class B, Division 2, 301-450 cubic inches-Stoddard-Dayton (Miller), 0:55 2-5. Class B, Division 1, 450-600 cubic inches-Knox

(Denison), 0:53 3-5.

Class F. Division 2, 202 cubic inches and less-Velie (Stickney), 1:00.

Class F, Division 1, 390 cubic inches and less— Stoddard-Dayton (Miller), 0:56 2-5. Class F, free for all—Chadwick (Lengle), 0:50 3-5.

Amateur Championship-Thomas (Greiner), 0:53

# Indianapolis Enforces Registration.

Enforcement of the automobile and motorcycle registration ordinance in Indianapolis began on August 10, and it is estimated that 5,000 persons will have to be registered. A badge and an engraved card giving a de-/ scription of the person to whom issued will be given to each driver, and the fee will be \$1. The registration will not have to be renewed unless the former license is revoked for violation of the automobile

The ordinance requires that every person be registered, whether the owner of a car or motorcycle or not. The police have adopted an arbitrary rule that the badges must be worn in a conspicuous place, threatening to stop all drivers who do not wear badges.

In applying for registration the applicant is required to give the following information to the Board of Public Safety: Name, address, sex, color, date of birth, whether automobile or motorcycle is to be driven; kind of power, length of experience in driving, whether experience has been in driving in cities, whether or not applicant is familiar with laws governing automobiles and whether or not applicant has ever been arrested for violating such laws. Each application must be indorsed by two freeholders who know the applicant to be a competent person to drive.

# Garage Notes.

P. P. Belt has opened a garage and repair shop in Fredonia, Kan.

William Parkinson has purchased the garage business of the Overland Motor Car Co. at 16 Railroad place, East Orange, N. J., from Charles Reiss.

E. E. Lincoln, of the York (Pa.) Auto Co., has let contracts for a new brick garage on Lincoln avenue, between Seventh and Eighth streets.

The Franklin Motor Car Co., of Philadelphia, have bought a building site 40x120 feet at 3430 Chestnut street, on which they plan to erect a garage.

Smith & Morgan, Youngstown, Ohio, whose present headquarters are located on Tod avenue, have let contracts for a new garage building on East Front street.

West, Vail & Lincoln, Decatur, Ill., who some time ago built a 44x40 foot garage building, found themselves cramped for room recently, and are now erecting an 18x50 foot addition.

Stuart Pilcher, Nashville, Tenn., has secured the State agency and will shortly erect a garage, but for the present will make his headquarters at the garage of the Tennessee Automobile Có.

Brad McLeod, a railroad engineer, will shortly open a garage in Delphos, Ohio, in the Wulfhorst Building on North Main street. Nicholas Dienstberger will have charge of the place.

Fred Leinhard, Bellevue, Ohio, has purchased a building site on Main street and will erect a garage building. A salesroom in the building will be in charge of Charles Lamn, of Clyde, Ohio.

The Carolina Auto Co. has been organized at Charlotte, N. C., to handle Rambler and Regal cars. A salesroom and garage is now being erected on South Church street on a lot 50x150 feet.

The Miller Machine Co., a garage concern of Defiance, Ohio, has leased the old bicycle factory in that city and begun the manufacture of a large touring car, to be known as the Defiance "40."

The H. H. Franklin Manufacturing Co. has opened a Buffalo branch at 683 Main street, in charge of George Ostendorf. Mr. Ostendorf has been connected with the Franklin Co. for upward of four years.

Arthur Howard, who formerly represented the Ford Motor Co. in Joliet, Ill., and then gave up the agency, has reassumed his connection with the Ford Company, and will also handle the Brush runabout.

The White Co., of Cleveland, O., will erect a two story and basement fireproof garage building in Dallas, Tex., at a cost of \$50,000. It will be equipped with steam heat, electric light and power and an electric elevator.

C. L. Lidders will open a garage on Eighteenth street and Fourth avenue, Rock Island, Ill. A new building 25x152 feet will be erected. Mr. Lidders has planned to take the agency for a number of

cars. This is the seventh garage in Rock Island.

The New York branch of the H. H. Franklin Manufacturing Co. has leased a five story and basement building on Eightieth street, just west of Broadway, which will be used as a repair shop. The building has a frontage of 30 feet and a depth of 100 feet.

The Stevens-Sowers Motor Car Co. have been organized in Boston and secured headquarters at 821 Boylston street, from where they will handle the retail sales of Jackson cars in Boston. The former Jackson salesrooms at 26 Tennyson street will be used as a repair shop.

The Lemly-Mills Auto Co, have opened a new centrally located fireproof garage at the corner of East Houston and Nacogdoches streets. San Antonio, Tex. They have the agencies for Pennsylvania, Ford and Hupmobile cars, and request catalogues from accessories manufacturers.

The A. Eliott Ranney Co., of New York city, who recently took on the Hudson agency, in addition to that of the Elmore, have removed to larger quarters at 1928 Broadway. They formerly

osed of an allotment of seventy-five Elmore cars

tion for 400 Hudson cars, which naturally calls for more space.

Walter E. Cimiotti has opened a garage at 2906 and 2908 Broadway, New York. The building is 50x100 feet, fireproof, with air pressure system for inflating tires installed throughout the building. Lockers are on the balconies. The building has canacity for 100 cars.

has capacity for 100 cars.

The Mitchell Automobile Co., of Milwaukee, has started work on the erection of a garage and salesroom at Broadway and Martin street, adjoining the site for the new \$150,000 Central Fire Station. It will be of fireproof construction, one story high, and cost \$7,500.

The H. H. Franklin Manufacturing Co. have opened a local sales office in Syracuse, N. Y., in charge of George E. Messer, who was formerly district representative for the company in Kansas, Nebraska and Missouri. Heretofore the Syracuse territory has been covered direct from the Franklin factory.

The Essex County (N. J.) Overland Co., Newark, N. J., of which William F. Ackor is president and manager, has closed a deal for handling the Overland and Marion cars in Essex County outside the Oranges, Glen Ridge and Bloomfield, and will shortly open a salesroom and garage on Halsey street.

The Protheroe & McGinnis Auto Machine Company has been organized at Baraboo, Wis., by Robert W. Protheroe and James F. McGinnis Mr. Protheroe has been engaged in general machine work and has been agent for the Buick for several years, and Mr. McGinnis has purchased a half interest.

Bids for the erection of the new factory of the DeSchaum-Hornell Motor Co., at Hornell, N. Y., were opened on August 2 and ranged between \$26,700 and \$31,835. The buildings are to be completed by the middle of November. They will be of tile, brick and concrete construction and absolutely fireproof.

The McPherson (Kan.) Automobile and Garage Co. is erecting a new garage building 50x120 feet on North Main street. The floor of the garage is of brick, while the washstand has a cement floor. In the rear portion of the building there is a 50x30 foot repair shop. W. O. Talbott and N. J. Lorenson are the members of the company.

The Minneapolis Motor and Truck Co. has placed the contract for a three story manufacturing building of cement block construction, 165x275 feet, and two smaller buildings for the finishing department and the power plant respectively. The aggregate cost of the three buildings is said to be in the neighborhood of \$100.000.

The Bryant Motor Company, Waterloo, Ia., will erect a garage building on Jefferson street, between West Fourth and West Fifth streets. It will have a white enameled brick front with terra cotta ornaments, while the walls will be of cement blocks. The company has the agency for the Chalmers-Detroit car. Frank Bryant is manager.

The Auto Storage and Repair Co., Minneapolis, Minn., has leased space at 717-719 Hennepin avenue, where the Pence Auto Co. was formerly located. This company was organized to supply the demand for storage created by the recent ordinance making it unlawful to leave a car stand in the street. O. M. Holden is manager of the new company.

work on a new brass foundry building on its Rand drill property in Tarrytown, N. Y. The foundry is expected to be completed about September 1, and will employ about 100 men. The company formerly purchased its brass fastenings, but to insure prompt delivery it will now make the castings itself.

The Vanguard Automobile Supply Co., of Joliet, Ill., of which Charles F. Jensen is president, has decided to locate in a former mattress factory in Desplaines street, that city. At one time there was some talk of the company removing to the East, but it finally decided to stay. The space vacated by the company in its old building will now be used by the Steinhart-Jensen Company for shop purposes. The Vanguard Company will manufacture wind shields.

C. C. Slaughter, St. Louis agent for Stearns cars, has leased a garage in course of construction at 1026 South Olive street, at \$200 a month for five years. The building will have a frontage of 50 feet and a depth of 155 feet and will be one story high.

John S. Lazarus has sold the Meridian Place Garage, in Indianapolis, to C. W. Allison and A. L. Duggan, who have renamed it the Twenty-second Street Garage. It is located in the centre of the exclusive residence district and was built by Mr. Lazarus, a capitalist, for one of his sons.

#### Trade Personals.

C. L. Morgan has resigned as sales manager of the Auto Tire Security Co., of Chicago.

Lewis M. Crittsinger, formerly connected with the Chalmers-Detroit Motor Co., has joined the R. L. Morgan Co., Worcester, Mass., as purchasing agent.

Charles J. Forbes, of Cleveland, has resigned as secretary of the Ohio State A. A., and has been succeeded by Dr. A. B. Heyl, a member of the Cincinnati A. C. board of governors.

Joseph A. Anglada, a former member of the staff of THE HORSELESS AGE, has accepted the position of engineer and designer for the G. J. G. Motor Car Co., White Plains, N. Y.

R. C. Chidester, formerly connected with the Welch Brothers Motor Car Co., of Milwankee, Wia., has joined the Schreiber Motor Car Co., of the same city, as accretary and manager.

F. W. Steers, who was superintendent of the Oakland Motor Car Co. at Pontiac, Mich., for the past two years, has taken charge of the sales department of the W. H. McIntyre Co. branch in Minneapolis.

Fred C. Vanderhoof, who was formerly connected with the Philadelphia Ford branch and the Bergdoll Motor Car Co., has accepted the position of manager of the Philadelphia sales branch for Oldsmobile and Oakland cars.

John Almon and George Holland, of Decatur, Ala., have established an automobile service between Decatur and Curtis Wells, a mineral water resort 5 miles from Decatur. Large touring carare employed, and a number of trips are made every day.

Frank Bowen, who had charge of the agency department of the Ford Motor Co., New York, for a number of years, and was later connected with the sales department of the Thomas car department of the Harry Houpt Co. in this city, has joined the Carl H. Page Co., who handle the Chalmers-Detroit in New York.

Archie Hughes, formerly secretary of the Fos-Hughes Motor Car Co., of Philadelphia, has become vice president of the company, and John H. Fassitt has been elected a director of the company. Mr. Fassitt connected himself with the company as salesman some years ago, and later rose to the position of sales manager.

Frank Mueller, formerly superintendent of the Mack Motor Car Co., Allentown, Pa., and Joseph Matheus, who was employed in the engine department of the same company, are reported to have organized the American Eagle Motor Car Co. of New York, with a capital stock of \$150,000, of which they are manager and assistant manager respectively.

M. E. Crow, who was formerly connected with

M. E. Crow, who was formerly connected with the Elkhart Motor Car Co., of Elkhart, Ind., manufacturers of the Sterling car, has withdrawn from that company and organized the Crow Motor Car Co., of Elkhart, who will manufacture a car to be known as the "Black Crow." It is reported that two Indianapolis concerns have contracted for the entire output of the company for the ensuing year.

The International Engineering Co., 1779 Broadway, New York, have taken over the American agency for the Etablissements Lemoine, who manufacture axles, springs, forgings, etc. The agency was formerly held by Lavalette & Co.

According to J. S. Bretz, who is handling the U. & H. magneto in this country, of 264 models of American cars of the season of 1909 selling for over \$1,500, only thirteen were not fitted with a magneto regularly or at the option of the pur chaser without an added charge.

NUMBER 7

# Block Construction in Cylinders.

By N. C. DAY.

"Non-Bloc," writing in a recent issue of The Horseless Age, appears to be familiar with only one early type of block construction, to judge from his communication. He enumerates the objections to it as follows:

- (1) Foundry, machine shop and sectional damage risk.
  - (2) Absurdity of pipe elimination.
  - (3) Inequality of expansion.
- (4) Need of additional radiator capacity. These are the dear old arguments presented in the dear old way. Modern block practice was founded upon these arguments. Every designer who adopted the practice fought them all out over his drawing board and explained them away to the powers that were. So, while refuting them, it may be well to investigate the modern and future practice and remove the scales from the eyes of many who still have the same delusions as "Non-Bloc." Let us take the objections seriatim.

Foundry uncertainty—that is, an increase over the percentage of scrappage that occurs every day in every kind of work—is only present with an innovation in foundry work. This same argument has been brought up time and again in connection with siamesed cylinder construction, yet today the siamesed type of cylinders is predominant. The foundry risk and the machine shop risk are dependent entirely upon the design. The design which minimizes both is by the better designer. This applies to both the block and the pair castings.

Before going into the details of these matters let us understand our terms. Block construction to me means four or more cylinders cast as a unit. Siamesed or pair construction indicates the general construction with two cylinders cast together. In unit construction each cylinder is separate, with its own water jacket. These, I think, are the generally understood meanings of these terms.

# RELATIVE COSTS.

If we consider a T head cylinder type of each construction with integral water jackets, we have in each case cores within cores. With the single or unit construction the passages for intake and exhaust are, as a rule, simple bends, and may, if desired, be made in one with the cylinder and valve pocket cores. The water jacket core must be made in two halves in any case, pasted together about the central core, and must be supported at at least three points. This

makes the simplest form of cylinder molding, and the design involves less volume of metal to handle, less area of thin wall, less risk.

Now take the siamesed arrangement. We have cores within cores—a cylinder core, a jacket core in two halves and separate intake and exhaust port cores. The pattern is more complicated and the jointing of the water cores is also a little more complicated. The risk of metal not running is apparently higher, but any good foundry accustomed to such work will make the same price per pound as on unit cylinders, and give the same guarantee.

We now come to the block type. We have exactly the same conditions as with the siamesed type, aside from the necessity for larger areas of thin metal; but again we have the condition that, provided the patterns are approved by the foundry, and provided the slight changes that may be deemed necessary by the foundry are made, the price per pound still remains the same, as does the guarantee.

Hence, comparing the various types, we find that the relative weights are as I to 11/4 to 11/2, in good practice, for the block, the siamesed and the single construction, respectively. Therefore, if the cost of a four cylinder block be \$10, two pairs will cost \$12.50 and four singles \$15. The cost of the patterns will be as 1:21/2:31/2 for the single, the pair and the block. Depreciation on these, however, will be slightly less for the block, as the other patterns are lighter and so more prone to damage. Taking the cost of the single pattern as \$100, and the others in proportion, and supposing that 1,000 castings can be made from each pattern, we find that the additional cost per piece will be 10 cents, 221/2 cents and 35 cents, respectively, increasing the total foundry cost to \$15.40, \$12,95 and \$10.35 for the different types. These figures prove that the foundry risk, as it affects the manufacturer, is inconsiderable, except in its bearing upon machine shop risk, which risk we will now investigate.

# MACHINE SHOP RISKS.

The greatest machine shop risk is that of finding a foundry defect after work has been done upon the casting toward finishing it. If such a defect be found it is permissible to demand a new casting for it, but there is no means of retrieving the loss due to the work spent upon machining unless it happens continually, in which case

the cheapest remedy is a change of foundries, the more expensive a lawsuit.

Obviously the scrapping of a single block casting is a more serious matter than the scrapping of a unit, provided it occurs at the completion of the piece; but let us see how much this actually amounts to, inasmuch as the casting itself is a "no-charge," except as far as freight and work done is concerned.

On a unit we have the following operations: Cylinder boring, flange facing, head facing, intake and exhaust port facing, water intake facing and valve port boring. On a block we have the same series of operations, except that there are four cylinders, probably four exhaust ports, as a rule, but one intake port and one water intake, and four sets of valve ports to be bored. One milling operation is commonly performed with any type of cylinder. Then comes the boring, and it is during this operation that at least 90 per cent. of the faulty castings are discovered. The primary milling operation is more lengthy on the block type of motor, but the additional cost may readily be expressed in cents and mills.

Now we come to the boring. Boring is at present almost universally done on a double spindle boring mill, often a double operation mill. In manufacturing units two are handled at once, and on a block two cylinders are handled at once. As a rule, the first heavy cut in each case will "tell the tale." The work stops right there. Very little has been spent in either case, but the risk, except for the possible time loss, is the same in both cases.

### REDUCED HANDLING.

But think of the difference in handling! One setting for each operation finishes the block, while the number of settings is multiplied by four for the same work with the unit. Also, remember that the manufacturing limits for port face distancing in the case of the block need not be drawn so fine as with the units, for, though they be exceeded, the faces are still in one plane, and will remain so; whereas any variation on the part of the unit cylinder port faces, or variation in truth on the part of the base flange, will be extremely annoying at the time of assembling, and, worse than that, a trouble breeder for the manufacturer from the test block to the last resting place of the engine.

Beyond this the machine shop risk is a matter to be settled between the engineer and the tool designer. Obviously it is not desirable to have any light projections from a block, but this applies equally to the unit. It is better to have all operations in planes at right angles or parallel to each other, since multiple operation machines may then be used.

I write this in the light of a manufacturer who can equip for any type. The block construction is a thing not to be lightly undertaken by one having small equipment and no capital to invest in special tools. To be a success the block type demands good equipment for its handling, whereas the best that can be said of the unit type is that it is capable of manufacture in a jobbing plant.

#### RISK OF ACCIDENT.

Now look at the sectional risk. "Non-Bloc" refers to a scored cylinder brought about by lack of lubrication and the expensive renewal necessary. In the first place, my experience teaches me that if any one cylinder is damaged by lack of lubrication the other three are in a sad state, too, and it is better to renew all four. In the second place, granting such a condition to arise. it is cheaper in the end to renew the block, for, though its cost be higher (price lists show that the difference is small), the customer can assemble his engine again with the new block and be sure that it will run as well as it ever did. If he replaces or has replaced a unit it is a thousand to one that his engine will never run as well again.

### ADVANTAGE OF BLOCK TYPE.

The best argument in favor of the block type is that it never has air leaks in the intake system that cannot be located with certainty and stopped. The most insidious. elusive fault that can develop in an internal combustion engine is an air leak, no matter how slight, anywhere between the carburetor and the inlet valves. If you don't believe me, just try glands on the valve stems. With an integral intake there is only one joint, or there are at most two, to be looked after and to give trouble; with a pair type there are three or four. Pair type engines have been more satisfactory than unit built ones, chiefly for that reason. The block is better than either for regular running for that reason alone, apart from any advantages it may have.

This discursion from my heading answers the second as well as the first objection, but it is necessary to look at the "elimination of pipes" objection more fully. The real object is not the elimination of pipes, but the water jacketing of pipes. The pipes are there just the same; so far as mixture distribution is concerned there is little difference, and if any it is in favor of the enclosed manifold. As far as exhaust pipes are concerned, only one maker in this country has the exhaust passage in one with the block. The invariable rule among designers is to dispose of the exhaust as quickly as possible, get it out of the water jacket by the shortest path offering the least area; a rule that holds good. no matter whether a block pair or unit em be used.

Our friend "Non-Bloc" is entirely at sea in talking of the abolition of pipes. The only thing that would militate against the cast-in pipe is its comparatively rough interior surface, but the majority of inlet pipes are castings, anyway, without the advantage of the water jacket.

#### UNEOUAL EXPANSION.

Now as to inequality of expansion. Let us grant that we have a block in which the exhaust ports are short and direct, in which our water jackets are not tied to the cylinder columns and the contour of which is reasonably symmetrical—points which are the sine qua non of any cylinder design.

Suppose such a block to be in working condition. Without water we should find our exhaust ports and combustion heads hotter than the rest of the cylinders, the hottest being the curve of the exhaust port, the coolest the valve pocket on the intake side. This condition would exist in each cylinder. The water jacket wall on the exhaust side would heat from its junction with the exhaust ports, and from its connection with the valve plug bores. It would duly expand, tending to curve the axial line which normally would run through the centres of the cylinders. The exhaust side of the cylinders would by conduction be hotter than the intake side. Consequently each cylinder would have a tendency to be concaved on the inlet side.

Now imagine the same conditions with the jackets filled with water. Apart from any pump influence there would be a constant replacement of heated water with cooler. Consequently, until the boiling point was reached, and granting an absence of steam locks and obstructions, we should have a fairly even temperature of jacket water which, though it does not necessarily mean an even temperature of cylinder and combustion head wall, does mean a great leveling of temperatures, so that the distorting effect is slight enough to be entirely neglected.

Supposing, however, that it is great enough to concave the motor axis slightly, this would have no discernible effect whereas vertical distortion with obvious detrimental tendencies probably occurs in each and every type, and yet is disregarded. Hence, though the exhaust pipe be cast integral with the cylinders, its effect need not be a matter for disparagement, except for its effect upon the maximum temperature of the cooling water.

We have heard a great deal in days gone by about cylinder distortion under working conditions, yet it is ludicrous when one remembers that to this day many makers use a solid exhaust pipe and clamp it tightly to the exhaust flanges, which will cause a great deal of distortion a few minutes after the motor is started.

### RADIATOR SURFACE NEFDED

Now for the last count—additional radiator surface necessary. Why this should be so is hard to see. The jacket volume of a block is, as a rule, greater than that of any

other form: the block jacket is free from obstructions and less liable to become inefficient from deposits. The water is subjected to a definite cooling influence from the enclosed inlet pipe. The flow being unobstructed, the head necessary for circulation through the radiating system is less, and thus power may be saved. The block type is par excellence the construction adapted for thermo-siphon circulation. With this system not only is the power necessary to drive the pump saved, but some of the waste heat is utilized. The development of heat is no greater in a block motor than in any other type; its transmission of heat to the cooling water is more uniform. Why, then, should the radiator need more capacity?

Apropos of radiator capacity "Non-Bloc" may not know that this is more a matter of fashion than anything else. Chassis construction is nearly standard, radiator form is rapidly becoming more so. The width of the radiator is nearly fixed by custom and necessity, and certain heights are necessary for appearance' sake; likewise, certain outlines within narrow limits. Radiator capacity, then, is a question of radiator thickness. Radiator thickness is variable only within narrow limits with the cellular type, for the reason that special lengths of radiator tube for cellular radiators are difficult and expensive to get. Vertical tube radiators alone are flexible, but if the tube tiers are increased comparatively little is gained by the addition of the rear tubes. You will find little or no difference in the size of the radiator for a four cylinder, 5x5 inch engine and a six cylinder, 5x5 inch engine, since any difference would upset two things, viz., standard appearance and manufacturing cost. Such things are adjusted, if at all, by varying the pump capacity, or, if that is inconvenient, by changes in the fan draught. Doubling of the heat loss of the motor to the jackets is never allowed for by doubling the radiator surface.

# FAVORS THERMO-SIPHON CIRCULATION.

But to return to the block construction and radiator capacity. Since the heat developed by a block motor is not more than that developed by any other type, there can be no valid reason for increasing the radiator with any system of circulation; but where the thermo-siphon is used the block has a tendency to decrease the radiator need rather than increase it, for the primary needs of every thermo-siphon system, volume and ease of flow, are both provided automatically in the block motor. The most serious defect in a thermo-siphon system is a water leak, since the system is inoperative without a continuous aqueous circuit. The risk of such a defect is minimized with the block, since the water joints to the engive need not number more than two, as against greater numbers with other constructions, and, besides, the vibration to which they are subjected is less severe, and twisting strains are entirely absent. Hence the jacket volume being greater, the flow

.

freer, the opportunity for using liberally sized water leads greater, the vibration less racking, the water joints fewer, the chance for fatal leaks less—may not the radiating system for a block motor be designed to operate with less chance of failure than that of other types?

If "Non-Bloc" will ponder the question I think he will see that even the enclosure of the exhaust pipe may, with small motors, have a useful effect, for, being toward the cylinder head, the heat it imparts to the cooling water may materially aid the flow in a thermo-siphonic system. It is easy to see that its distortional effect is small if it is in contact with the cooling fluid. It will undoubtedly raise the mean temperature of the cooling water, which in itself is an excellent thing, inasmuch as almost all small motors run at too low a mean jacket temperature for the highest fuel efficiency.

#### RIGIDITY A FEATURE.

Let us consider some of the other advantages of the block motor. There is no need for ponderous crank case construction with it, since its form provides all the necessary rigidity. It can readily be designed to be supported on the main frame, by tubular cross members, for instance. The abolition of the sub-frame is desirable, yet hitherto a questionable move, since long crank chamber arms have been subject to breakage.

The block motor may be made shorter; so short, in fact, that a two bearing crank shaft may be used. Granted that the two bearing shaft has sufficient stiffness to support the bending strains imposed upon it, is it not an advance in mechanical efficiency? In any case the rigidity of the block tends to preserve the bearing alignment.

This same reduction in the over-all length of the motor permits of reducing the wheel base without changing the body location.

Considered as a manufacturing proposition, many less parts have to be handled. The block motor is an ideal proposition to "tool for"; less stock needs to be carried, there is less chance for trouble once the motor leaves the factory; it is less trouble to assemble, it is less costly, and last, but by no means least, there is less chance for the user to tamper with it when he gets it.

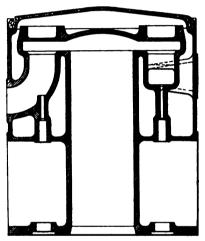

# FULLY ENCLOSED MOTORS.

The block motor is also much cleaner than its rival. It has no copper pipes and no bright parts to attend to, but is symmetrical and smooth, and requires a minimum of attention. Consider the ease with which all the valve mechanism may be enclosed, easy of access, yet protected from dust, lubricated and hidden from sight. The fully enclosed automobile motor is as surely the motor of the near future as the fully enclosed electric motor is the motor of today for traction work. I have heard it asserted that the fully enclosed motor has no high lights to take the eye, that it looks like a box. Let it! It will run sweetly and silently when the motor of appearance has pounded itself to the scrap heap.

A block motor may be made lighter, I believe, than other forms, but an extra light motor is not an unmixed blessing for automobile work. The block motor is, as a rule, cast iron throughout, crank case and all, and this is good construction. It is always hard enough to properly "spring" the front of a light car, but with a motor it is a case of hope deferred; an additional 50 pounds helps a great deal, both with springing and steadiness. What we need more than lightness are rigidity and permanent alignment.

#### A SUGGESTED DESIGN.

Having gone so far in discussing block construction, I would like to suggest a block type that to my mind has many points to recommend it. Its chief difference from usual practice is the feature of complete water jacketing—port plugs and all. The section herewith clearly shows the idea.

BLOCK CYLINDER DESIGN.

The top water cover completes a total water jacket about the cylinders. Apart from the fact that such a design would provide the simplest form of block casting it would permit of higher compression being satisfactorily used, would remove hot spots and make a much cleaner engine than any other form.

The valve guides would be water jacketed and packed, the valve springs acting as an automatic take up for the glands. Covers can easily be applied to encase the valve stems, springs and tappets.

It will immediately be claimed that the construction is one tending to inaccessibility. That is true; and were valve grinding a daily or even weekly necessity it would not be permissible. But valves rarely need grinding, and the jacketing of the port plugs would make it much rarer still. In any event, the top cover is easily removed, since, as a rule, all valves are ground at the same time.

Sheboygan, Wis., now has 146 motor cars, with a population of 22,000. On August 15, 1908, only seventy-two cars were listed.

# Maintenance and Repairs

#### Brazing.

By A. P. Press.

Although one of the oldest of shop operations brazing is nevertheless one of the least understood. Every smith from Tubal Cain down could braze a piece of work, but how many of them can tell before they do it that it will be a good job and what pressure it will stand? A joint well cleaned and brazed will stand strain nearly equal to the tensile strength of the metal itself. A machine steel collar I inch long with a I inch hole brazed to a piece of steel tubing stood a strain of 50,000 pounds, with no signs of starting.

The first requirement for a good job of brazing is to clean the work thoroughly; that is one-half the secret of a good brazed ioint. No brazer can make a good job of a dirty or poorly cleaned joint; he may boil out the dirt and grease, and finally get a good joint of it, but it is a sloppy way to go about it. The cleaning operation should be a mechanical one; that is, not wholly a wash or dip, but it should be finished with a file and emery cloth. Sand blasting is the ideal method for cleaning work for brazing. It not only cleans the metal of all scale, but it penetrates the pores of the iron itself, and leaves it in a condition to receive and hold the brass, and also does it at less cost than any hand method.

### FLUX.

While good borax, burnt and ground fine, makes a good flux, there are several compounds on the market that will give better results than the borax. If wanted for a quick job that is to be brazed at once, mix borax with wood alcohol, or, better still, with what is known as "Columbian Spirits," but if this is not at hand, clean water is nearly as good. Mix the compound or borax to a thin paste, and apply with a thin brush, so as to wet thoroughly every part of the joint before the same is put together. After the job is assembled and pinned, paint about a half of an inch each side of the joint with a mixture of machine oil and black lead. This holds the flux in place, and also stops the spelter from running each way from the joint and leaves the work so that it is easier to clean and finish up. A joint should be pinned to hold it in place while being brazed. Run a No. 29 drill through the job and use an 8 penny wire nail. This makes a good pin for any work of I to 2 inches diameter.

### HEAT.

Any clean fire will do for a job of brazing; it may be gas, coal or oil. A gas fire is by far the best, and though the cost is greater than for an oil or coal fire, better results can be obtained by the use of it. There is on the market at least one brazing table that will effect a saving in gas and

still turn out good work. It is simple, cheap and it will pay for itself in a very short time. Put the heat on the heavy part of the work first, so as to bring it nearly up to the brazing point, so that when the heat is put onto the joint the heavy metal will absorb it and cool off the part to be brazed. Bring it slowly up to a bright yellow heat, and as the spelter and flux begin to melt, dip the brazing wire in a mixture of the spelter and borax or brazing compound and apply to the joint. Before dipping the wire hold it in the flame so as to heat it as near as possible to a melting point and still not melt it. As the flux and spelter melt turn the work so it will run to all parts of the joint, and while still turning remove it from the fire and keep it in motion till it "sets." If it is a large job that cannot be handled in this

#### CLEANING OFF THE WORK AFTER BRAZING.

manner turn off the heat and allow the blast to strike the work and cool it off.

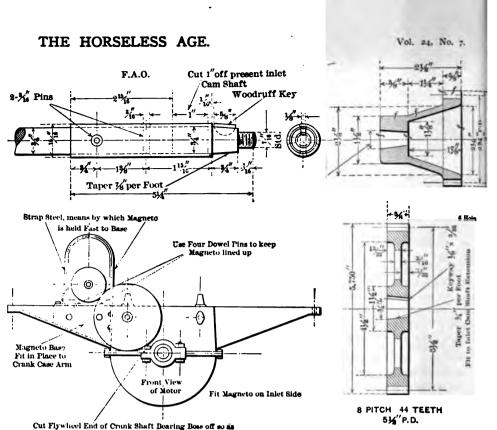

There are several methods of cleaning the work after brazing. If you have a sand blast use it, as it has no equal for that purpose. The next best method is pickling in a weak solution of vitriol and water, about I quart of vitriol to a barrel of water. This is not so good a method as the sand blast, especially for tube work, as any acid left in the tube eats the metal and weakens the ioint. The sand blast leaves the work clean and ready for the file, and also shows up all the imperfections in the brazing. An old fashioned method of cleaning the work is as follows: When the work is nearly cool, dip it in a pail of soap suds; this starts the flux and impurities and does not harden the metal. It is not recommended as good practice.

### COST.

When work is done on the premium or piecework basis the cost can be made very low, as high as 1,800 to 2,000 joints being brazed in a day of ten hours. Ordinary automobile work can be brazed at a cost of 50 cents per hundred for small work and as high as 4 or even 6 cents per joint for the larger parts.

### DIP BRAZING.

Dip brazing can be practiced on certain classes of work, and at one time time was used extensively in the bicycle trade. The cost of the work is far lower and the cost of cleaning is a trifle as compared with torch work.

PARTS USED IN FITTING U. & H. MAGNETO TO MODEL S BUICK.

#### CAST IRON BRAZING.

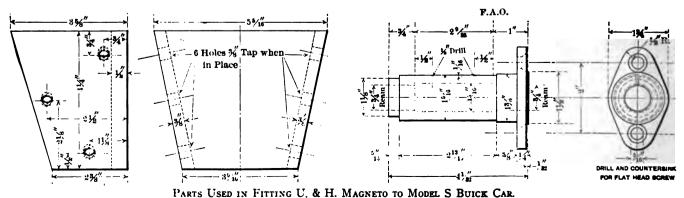

to Clear Cam Shaft Gear

Almost any kind of a broken joint of cast iron can be brazed, and, if well done, will be stronger than it was before breaking. The broken jaw to a 41/2 inch bench vice brazed some two years ago has been in constant use ever since, and shows no signs of giving out. To make a good job, first heat the work to a dull red; this takes the dirt and grease out of the pores of the metal; next clean the work with the sand blast or with a wire brush if the blast cannot be had; next apply the brazing powder to the broken surface of the work. This leaves the iron in condition to take and absorb the spelter. Then fasten the broken parts firmly together, either by putting in a screw or by holding them together with a twisted wire. Now place in the fire and bring up to a bright yellow heat; in fact, almost to the melting point, and apply the brazing compound. Then shut off the gas and allow it to cool without moving. There are several cast iron brazing compounds on the market, but the method is practically the same with each.

# Fitting a U. & H. Magneto to a Model S Buick Car.

Many of the older and lower priced cars have no provision for fitting a magneto, and as this device needs a very firm foundation, in a point where it can be placed in driving connection with the motor, fitting of a magneto is often a rather difficult problem. Joseph Tracy, of New York, has fitted a U. & H. magneto to his 24 horse power Model S Buick car, and as the arrangement adopted by him may be of interest to other owners of cars, we describe it herewith. All of the parts necessary are shown by the accompanying working drawings.

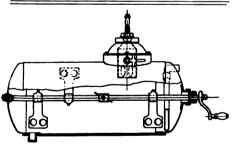

In looking the car over before commencing to make the drawings Mr. Tracy found that the only alterations to be made would be on the right hand side of the motor. Here the main feature in the way of placing the magneto was the shape of the curved gas inlet manifold. This was removed and replaced with a perfectly horizontal one, as shown in the photograph. There being no further use for the battery which was carried under the rear turtle

deck, it was removed also. The coil was removed from the dash, and as the magneto carries its own timer internally, the timer was removed, and the timer shaft hole in the crank case covered up with a plate cover, bolted on as shown in one of the drawings. The extension of the cam shaft which carries the gears to drive the magneto was carried out through a blind hole in the forward end of the crank case, and all that was necessary to do there was to remove the cover of the hole. The bed plate in the arm of the crank case on which the magneto rests was made of bronze, and after everything had been fitted it was found to be as easy to crank the motor, Mr. Tracy asserts, as it was previously to start on the battery.

Mr. Tracy has fitted a small Yale lock to the dash of his car which locks the bonnet in place and also cuts out the ignition. He also removed the spark lever and its connection, as with the magneto he runs on a fixed spark.

Henry Sturmey, the well known British manufacturer and writer, who recently returned home from a visit to Warsaw, Russia, where he secured an important order for taxicabs, reports that the one difficulty he had in arranging terms with the purchasers was in connection with the double horse power rating of his cabs, they being 12-16 horse power. The Russians simply could not understand how a motor could be a 12 horse power and a 16 horse power at the same time; they thought there was some trickery connected with the double figures, and Mr. Sturmey was asked through the interpreter to remove the "12" from the specifications before the contract was signed.

F1G. 2.

#### Construction Details of Motor Fire Engines.

By F. A. EISNER, M. E.

About a month ago the writer witnessed a demonstration of a modern fire automobile in Buffalo, and became so interested in the matter that he made up his mind to study the construction of the present fire automobile more closely. What impressed him most in connection with this demonstration was the immediate supply of water

which transports both the men and the hose. In the following I will give a description of the fire engine which was demonstrated at the time spoken of in Buffalo, and which, as I found out later, was constructed by the Webb Motor Fire Apparatus Company, of Vincennes, Ind. The chassis is a standard construction of the E. R.

Fig. 1.

thrown to a height of about 210 feet as soon as the connections were made and the fire engine was stopped, the absolute absence of smoke and the ease with which the machine was handled in all the different stages of the trial. Every horse drawn steam engine has certain weak points which cannot be overcome, but in order to give the atuomobile the advantage over this old fashioned vehicle these weaknesses ought to be eliminated in the designs of the motor fire trucks.

At present the most essential features are absolute running and pumping reliability, quick starting and stopping ability, and large capacity for carrying fire extinguishers, ladders, hose and other articles required in fire fighting. Furthermore, each engine ought to carry all the men required for making hose connections, regulating the speed of the pump and directing the jet of water in an efficient way, so that the car, when arriving at the scene of the fire, is not required to wait for another truck

Thomas Motor Company, of Buffalo, N. Y. The wheel base is 131 inches, with a total length of frame of 174 inches. The wheels are 40x6 inches, extra heavy, and carry quick detachable pneumatic tires. springs, of course, have to be pretty heavy, in proportion to the load carried. The main gasoline tank is a pressure tank, and is located in the rear of the car between the two rearmost cross members. The gasoline is forced from here through a pipe to a small gravity tank under the front seat. The engine is of the four cylinder type, with magneto and battery ignition, with a bore and a stroke of 5½ inches each, and is rated at 52 horse power. The clutch is of the usual Thomas construction, being a three plate disc clutch. There is a long connecting shaft between the clutch and the transmission, which latter is of the selective type. The rear wheels are driven by two side chains, and there are two external transmission brakes and two internal rear wheel brakes, the latter being operated by the brake hand lever. The construction of pedals and hand levers used for applying brakes and changing speeds is conventional. The above described chassis is used both for the chemical engine and the rotary pump, a description of which will be given later. The chemical engine is shown in assembly in Fig. 1.

The tank of the chemical engine is situated behind the driver's seat on top of the body panels, and in the rear of the same is located a basket or reel, according to special requirements, which is used for the chemical hose. Fig. 2 gives the assembly of this chemical tank and shows that there is in the dome of the tank a bottle of sulphuric acid which is turned over and emptied when the pump is to be started.

Fig. 3.

The contents of the tank consist of 30 or 40 gallons of a saturated solution of soda in water, and there is an agitator provided for which may be turned by a crank outside of the tank to more thoroughly mix the acid with the water when pumping begins.

The body of this truck also carries 1,000 feet of hydrant connection hose, two hand extinguishers, axes and ladders, and there is place for seven firemen in the seat, on the rear step and the running boards. The chemical engine is, of course, most useful for fighting small fires or where there are powerful hydrants, so that employment of a pressure pump can be dispensed with when fighting the flames. Where there are no sufficiently powerful hydrants in the neighborhood, or when the fire has become too large to be extinguished with small streams of water, a pumping engine will be required. An assembly of this truck is given in Fig. 3.

The pump is shown in Fig. 4 assembled on the frame, but without couplings, dome or hose connections, and in Fig. 5 disassembled. It will be seen from this figure that the pump is mounted between the transmission and the clutch, and is driven by means of a pair of spur gears, one of which is fastened on the left hand pump shaft, while the other is sliding on a square of the clutch connecting shaft, and can be thrown out or brought into connection with the pump gear at the will of the operator. The pump is a rotary pump, and the two pumping gears fit closely to the walls of the housing. The shafts are carried by ball bearings on each side of the housing, and the stuffing box is constructed in a very ingenious way, being very small and easily tightened. (Both the ball bearings and the stuffing box construction are

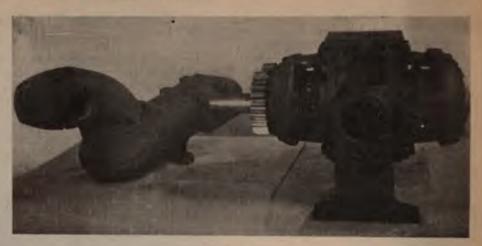

Fig. 5

covered by patents.) Outside of the driving gears the shaft of the pump is supported by a Hess-Bright ball bearing, mounted in an oiltight housing, which is carried by a special cross member bolted to the side members of the frame, and there is another ball bearing provided for which is used for stiffening the clutch connecting shaft and is carried by a second special cross member. This connecting shaft is, of course, of heavy construction, since in addition to supplying power to the transmission it must withstand a vertical pressure delivered through the pump driving gears. The smaller pump driving gear is, as I stated before, slidable on the square part of the clutch connecting shaft, and is put in action by means of a fork which is fastened to a shaft held in place by bearings bolted to the side members of the frame, and to which is attached a hand lever. Through this shaft, which is constructed as a steel tube, goes another shaft, bearing on the right hand side a second hand lever, and on the other side a small lever which throws the clutch out when the car is standing and the pump is not in action. This second pair of hand levers is seen in Fig. 4, and is placed somewhat behind the first pair of levers, which are of the normal construction, one being used for gear shifting while the other applies the rear brakes, and the only difference is that the brake shaft is not connected in any way with the clutch throw-out. This connection is left off because the car has to be held in place securely by means of applying the rear wheel brakes, and at the same time the driving shaft is required to revolve in order to drive the pump. It is hardly necessary to state that the transmission is running free while the pump is driven, and vice versa.

The question of how to cool the engine while the car is standing and the motor is driving the pump is solved in a very ingenious way, there being an eighth of an inch tube connection between pump and motor cylinders, through which is forced a constant stream of cold water as long as the pump is working. The water flows from the front cylinder to the radiator and leaves the latter through the wide overflow pipe.

The pump described above is guaranteed to throw 700 gallons of water per minute, but it actually throws 1,000 to 1,100, and produces a vacuum of 26 feet. The weight of the car fully equipped, with tanks filled, but without hose or men, is 6,000 pounds, and there are places provided for ladders. hand extinguishers, lanterns and axes and 1,000 feet of hose is carried in the body. Furthermore, there is room for seven men, as stated before, so that when the engine reaches the scene of the fire it has neither to wait for the hose wagon nor for the truck which transports the firemen, and all the men are available as soon as the ear stops, except one who has to handle the pump, but nobody is needed to hold the horses, stir the fire under the boiler or do similar duties. Larger cars, with more powerful pumps, are equipped with six cylinder motors.

## Methods of Determining the State of Charge of Vehicle Batteries.

The most animated discussion at the Chicago meeting of the Society of Automobile Engineers centred around the question of the best means for determining the state of charge of automobile batteries. From the list of papers presented at the meeting it will be seen that quite a number related to some phase of electric vehicle work, and it was evident at the meeting that among those in attendance many were interested in this branch of the industry. This may be taken as another proof of the present activity of the electric vehicle branch of the industry, which has been referred to repeatedly in these columns.

Recently a tendency has been noted to use electric vehicles more for drives of considerable length into the country, instead of merely for short business or pleasure trips in the city, and this necessitates the provision of some reliable and convenient means for ascertaining at any time how much of the original charge still remains in the battery. When the battery is nearly discharged the driver will be apprised of the fact by a perceptible reduction in the vehicle speed; but if he is on a trip to some

point at a great distance from charging stations this warning comes too late to be of service. A charge gauge or charge indicating device is really essential for a vehicle used for such service. If the vehicle battery were fully recharged at the end of every trip the odometer might be used for keeping track of the charge, but it is at best a very imperfect instrument for this purpose, as the mileage which a battery will give on one charge varies considerably with road conditions, load and method of driving, and the odometer, of course, measures only the mileage accomplished.

There are at present three methods available for determining the state of charge of a storage battery, viz., a voltmeter test, a hydrometer test and the use of an ampere hour meter. Up to lately the voltmeter test was most largely depended upon, but the voltmeter reading is not at all a satisfactory indication of the state of charge of the battery. Until about three-fourths of the charge is taken out of the battery a relatively large discharge results in only a very small drop in voltage, and the voltmeter indication is therefore a rather uncertain index of the amount of charge remaining. Near both ends of the discharge curve the voltmeter serves very well; it indicates quite accurately when there is very little or nearly a complete charge in the battery, but near the middle of the curve, where the greatest accuracy is often required, as when a run is made out into the country and the driver wants to know when to turn back, the voltmeter method is not at all sensitive.

The defect of the voltmeter is absent in the hydrometer method, which is based on the fact that the density of the electrolyte varies from about 1.200 at charge to about 1.120 at discharge. Sulphuric acid is withdrawn from the electrolyte and taken up by the active material in direct proportion to the discharge current, and the density of the electrolyte varies therefore practically at a constant rate with the discharge between the two limits. The objections to the hydrometer method are based mainly on its inconvenience. It is necessary to remove the plug from one of the cells and siphon out some of the electrolyte, and after a reading has been taken to drain the electrolyte back into the cell and screw back the cover plug. This method is not at all adapted for the use of ladies, many of whom now drive electric runabouts.

The latest and best method of determin-

ing the state of charge is undoubtedly by means of an ampere hour meter. Until recently there was no instrument sufficiently rugged to withstand the vibration of road work, all such meters being designed for house installations. It seems, however, that now the problem has been solved and a simple, sturdy instrument has been produced that meets all the requirements of vehicular service. With such an instrument on an electric car it will be possible to utilize a greater percentage of the total charge stored in the battery, and the driver should enjoy more peace of mind than if he could only guess at the amount of "juice" remaining to carry him home.

#### Lubrication of Brake Linkages.

The development of convenient and complete provisions for the lubrication of motor cars forms a very interesting chapter in the annals of the automobile industry. Gradually the parts of the mechanism which have been neglected in this regard are receiving the attention which they deserve, but the work is not yet completed.

Upon the majority of cars no facilities are provided for the effective lubrication of the operative parts of hub brakes. These linkages are sometimes quite complicated, relating as they do to two sets of brakes and including a considerable number of bearings upon which move parts that are subject to very frequent use. No part of the car is more exposed to mud and dust than are these linkages, and their inaccessibility tends toward their neglect. Any looseness in the bearing pins of the levers forming these linkages gives rise to a disagreeable rattling, especially as these parts are not spring supported, and if the looseness resulting from wear progresses too far, or if the bearings become dry from an entire absence of oil, uncertainty in brake operation may actually develop.

These parts are generally lubricated, if at all, by means of the squirt can, oil being applied to the crevices between the moving and stationary parts, on the chance that it may find its way to the bearing surfaces. As the parts are always gritty, such lubrication is at least highly ineffective.

Upon a few of the later models it is to be noted that attention has begun to be paid to the lubrication of these parts. On some of the larger parts small compression grease cups are to be found, and upon the smaller members oil cups with spring retained caps are provided. This practice must be carried out consistently, and all

moving parts of the brake operating mechanism at the hubs must be cared for, or the result will be only partially satisfactory.

If an automobile is to wear well as a whole, every moving part and not merely almost every important part must be provided with means for insuring a clean oil or grease supply to the wearing surfaces, with the minimum of inconvenience upon the part of the attendant. In the case of a mechanism so essentially dirty as an automobile, squirt can lubrication of the hit and miss variety ought to be eliminated.

It is to be hoped that this practice of providing adequate lubrication for the rear axle mounted brake mechanism will be generally adopted in the interests of durability and satisfactory operation.

## Spring Suspension on Next Season's Cars.

The 1910 designs which have so far appeared seem to show that semi-elliptic front springs and three-quarter elliptic rear springs will be the most popular types during the coming season. Of course, there will, as usual, be all sorts of combinations. On some of the larger cars semi-elliptic springs will be used all around, while on a few of the lighter machines a complete equipment of full elliptic springs will be retained. But in the majority of cases the semi-elliptic springs will be used in front and either full or three-quarter elliptics at the rear. When full elliptic springs are used at the rear some means must usually be provided both for pushing the car and for taking the torque reaction, for, although both of these functions may be combined in springs of this type, there are comparatively few designers who care to make the springs heavy enough to withstand the stresses, most designers claiming that to do so makes the spring hard riding.

Where the three-quarter elliptic rear springs are used, however, the front ends are usually made stiff enough to push the car. This leaves only the torsion to be taken care of by external means. It is probable that even this can be well taken care of by securing the spring seats to the axle and making the spring somewhat heavier. This is often done with semi-elliptic rear springs, apparently with good results. The same objections may be urged as were mentioned in connection with full elliptic springs, but they apply here in a lesser degree, for only the forward part of the spring need be made heavy to take the torque and to deflect under the heavier

actions, while the rear portions may be arranged so as to give the necessary flexibility when passing over small obstacles.

Other tendencies which may be noted in the designs of next season's springs is that they are generally made wider for a given weight of car than formerly, and have less arch for a given length. Both of these changes tend to make the cars easier riding.

#### Forced Induction Motors.

In England renewed attention seems to be given recently to a principle in gasoline engine operation which in a somewhat different form was exploited by a number of inventors in this country in earlier years. Abroad it is referred to as the forced induction principle, and the chief characteristic is that the cylinders receive a greater charge per power stroke than the volume of the piston displacement at atmospheric pressure. Perhaps the simplest way of operating an engine on this principle is to draw the charge into the crank chamber of a double opposed engine and transfer it to the two cylinders alternately. As the pumping capacity of the crank chamber of such an engine against atmospheric pressure is twice as great as required to keep the cylinders supplied with charge at atmospheric pressure (neglecting the effect of gaseous friction), it is evident that a considerably greater charge than that corresponding to atmospheric pressure can thus be gotten into the cylinders in this way.

In the English engine above referred to the same object is attained in a somewhat different way, in that the engine is built with five power cylinders and one air compressor cylinder, and air is stored under pressure in a tank from where it is led to a sort of carburetor spray chamber, and thence to the engine cylinder. Consequently, the fuel, instead of being drawn out of the spray nozzle by atmospheric suction, is ejected by a powerful ejector action. The inventor claims for this engine that it produces a very much greater mean effective pressure than the ordinary engine, and that, since the power strokes overlap, the engine will start automatically in either direction, and no change gear is required on a car.

It seems to us that the abolition of the change gear, which seems to be a hobby with a certain class of inventors, is of very questionable advantage. It requires an exceedingly big engine in proportion to the weight of the car and the load to be car-

ried, and the tendency among owners seems now to be all the other way, owing to the great expense of such engines. The "forced induction" engine would, besides, be a less economical engine as far as fuel consumption is concerned, because the charge is expanded less than in the conventional engine. Taking this disadvantage in conjunction with the complication entailed by the compressed air installation, forced induction device and the spring supported and ring packed inlet valve guides, it would seem to us that the advantage of self starting is secured at rather too high a price, for cars of moderate size at least.

#### "Bench Assembled" Parts.

It is evident that in the present search for economical methods of manufacture the cost of assembling is receiving a good deal of attention. This is shown by the tendency to make the car from a number of "units," each of which may be quickly assembled on a special bench fitted for the work. Each of the units is secured to the frame by a few bolts which can be quickly fastened, so the actual work of assembling the chassis only takes a fraction of the time formerly occupied when other methods were employed. For this reason much less space is needed to assemble a given number of cars in a season, since the chassis assembly floor does not need to be nearly as large as formerly, and the sub-assemblies are compact and quickly handled.

Where the main work of assembling is thus sub-divided the workmen become more strictly specialists than where they more from chassis to chassis doing certain operations. Moreover, the working parts may usually be more accurately adjusted, so there is probably a saving in the time of running in.

From the standpoint of ease of repair and replacement the "unit" system of construction is superior to any other, so we may confidently expect to see it adopted on all cars used for business purposes as well as upon pleasure vehicles which are manufactured in very large numbers.

#### Coming Events.

August 31 or September 30—Milwaukee (Wis.)
Annual Orphans' Outing, Milwaukee A. C.
September 6-11—Lowell (Mass.) Annual Moss

Carnival, Lowell A. C.

September 15—Denver (Col.) Start of Flagts
Flag Race to Mexico City, Denver M. C.
October 7—Philadelphia (Pa.) Second Annual

October 7—Philadelphia (Pa.) Second Annual 200 Mile Stock Chassis Race in Fairmount Park Quaker City M. C.

November 6 to 13—National Automobile Show under the auspices of the N. A. A. M. at Atlanta Ga.

#### The Taximeter Cab in Chicago.

By E. L. W.

Chicago, "the city of distances," though at first rather chary about discarding the horse-drawn cab for the more modern taximeter cab, has gradually been forced to recognize the newer method of transportation.

Owing to the almost absolutely level topography and the unsurpassed boulevard system, the Queen City of the West has always classed as one of the best selling centres in the United States, especially for American cars, foreign cars never having secured much of a foothold in the Middle West The automobile livery or renting business has also thrived, and owing to the immense amount of capital invested in cars that were used exclusively for renting, when the taxicab first made its appearance in European centres, and in New York, the concerns interested in the livery business, whether using horse or motor cabs, naturally used their best endeavors to prevent it from gaining public favor. However, the traveling public gradually forced the various companies to adopt this cheaper and more popular means of transportation. and at the present time there are several large concerns with considerable capital behind them doing business in this line, and all of them are constantly increasing their rolling stock as the demand warrants.

A recent strike of the drivers of horse-drawn cabs and carriages greatly helped to establish the motor cab. During this strike it was almost impossible to even conduct a funeral without police protection, and the Chicagoans were treated to the novel spectacle of automobile funerals, bodies of hearses being removed from their usual running gears and placed on automobile chasses, the mourners, etc., following in either taximeter cabs or touring cars, for which latter a flat rate was charged.

The total number of taxicabs and touring cars with taximeter attached in service in Chicago is approximately 250. The total number of horsed cabs and hacks is 700. These figures are from the city clerk's office. As a number of concerns and individuals have not yet paid their wheel tax it is impossible to secure the exact number of either class, but the above figures are nearly correct. The wheel tax for either a taxicab or a touring car, either private or public, is \$20 per year. A license ice of \$5 per year is charged for hacking on streets. None of the operating companies conduct private service to individuals or clubs at a flat rate per month.

THE OWEN H. FAY LIVERY COMPANY.

One of the largest and oldest livery concents in the city, the Owen H. Fay Livery Company, who formerly operated some 200 horse-drawn vehicles and maintained stands at the most prominent hotels, having become disgusted with the numerous strikes and various troubles with their drivers, have gradually disposed of their stock of horseflesh and carriages, until they are now operating about thirty-five horse-drawn vehicles, and even this number is to be still further reduced, Mr. Fay stating that the only use they now have for the horse-drawn vehicle is to carry patrons from the various downtown hotels to the railroad depots. In the downtown section traffic is always more or less congested, and the horse-drawn vehicle can travel as rapidly as the motor-propelled vehicle, hence there will probably always be a few horse cabs used in this service.

The Owen H. Fay Livery Company's main office and stable are centrally located, at 53 Plymouth court, within a block of the Chicago Automobile Club, and in close proximity to the leading hotels. A branch office and stand are maintained at 244 Michigan avenue, which premises are also used as a salesroom, the company having the local agency for the Franco-American Taximeter Company and also the Central Western agency for Elmore cars. The main office and stable at 53 Plymouth court are located in a five story brick building 75x100 feet, which was originally used by the company exclusively for the horsedrawn livery business. At present it is being entirely remodeled into a modern garage and repair shop, which will be used exclusively for cars operated by themselves and when completed will be the largest and most pretentious garage devoted to the taxicab business in this section of the country. At the present time they are operating twenty-one Elmore taxicabs, ten Woods electrics, with taximeter attached, two large sight-seeing cars, and twenty Elmore touring cars. These latter have taximeters attached, and can be rented either as touring cars or taxicabs. When desired as touring cars a neat rubber cover is placed over the taximeter, shielding it from view, it being placed low on the side of the car adjoining the driver's seat. Special limousine bodies are at present being constructed for winter use on these touring cars. Mr. Fay expresses the opinion that within another year the stock of cars in operation will be tripled. During the summer months a victoria top covering the rear seats is in use on these cars, which gives them a very natty appearance.

All taximeters are attached to the front wheels. No special arrangement as to maintenance is in force with the manufacturers of the cars, but since the Fay Company are agents for the taxis they carry on hand a full line of extra parts. A mileage contract on tires was made when the company first started, but on account of the tires exceptionally giving more mileage than the contract called for, this contract has been discontinued. Quick detachable rims are used, but no spare wheels are carried. They operate their own vulcanizing department, which is in charge of

an expert secured from one of the large tire manufacturers. All inner tubes are repaired by him, but all casings go back to the factory for retreading, etc. Whenever a front tire needs replacing a tire is taken from one of the rear wheels and placed on the front one, and a new tire goes to the rear. The average mileage of the tires is about 4,000. Should a driver be careless enough to drive on a flat tire, he is instantly dismissed as an incompetent. This company have tried both commission and salary arrangements with their drivers, and have concluded that the best service is secured from the driver who receives a regular salary. It is claimed that the driver working on a commission basis rushes over his calls with but the one idea, of getting back for another load, and that the car is consequently subjected to rather harsh treatment as a rule. At the present time all drivers receive a straight salary. \$16 a week being paid to the drivers of taximeter cabs, and \$18 to those operating touring cars, with 25 cents additional per hour for overtime. A chauffeur found guilty of drinking when in charge of a car is instantly dismissed. As many of these chauffeurs were originally drivers of horsedrawn vehicles it has been necessary to enforce rather rigid rules in this regard. As is well known, the majority of "cabbies" were in the habit of drinking rather heavily, and relying on the good sense of the horse to always find its stable. The motor car, however, needs more attention, so that the Fay Company make it an "ironclad" rule that drivers must not drink under any circumstance while in charge of a car.

No hackney stands are operated by this concern. They have contracts with the Congress Hotel Company and the Annex, the Great Northern Hotel, Palmer House, Hotel Stratford, Hotel Brevoort, Union League Club and Chicago Club. At each of these places an employee is on hand to receive orders, and a private wire to the nearest of the two stations brings a car in a very short time. A commission is paid to the hotels for this exclusive privilege. It is necessary for the driver of a car to return to the station and check in after each trip; the meters are then read, and the car is looked over before responding to the next call. The rates of hire for from one to four passengers are:

50 cents for the first mile;

10 cents for each additional quarter mile; 10 cents for six minutes' waiting.

Four dollars an hour is charged for taxicabs, and \$5 per hour for seven passenger touring cars. Mr. Fay states that the dead mileage of cars going and coming from calls is the one great drawback to the taximeter cab business, as fully 40 per cent. of the total mileage of the cabs is dead mileage. The busiest hours are from 10-11 a. m., when the cabs are much used by business men for making rush calls, 2-3 p. m. (visits and shopping), 5-6 p. m. (to the limited trains), 8-9 p. m. (to theatres), and 11-12 p. m. (returning from theatres).

#### THE AUTO TAXICAB COMPANY

at 2441-2443 Michigan avenue, with a North Side branch at 733 Wells street, are operating fifty taximeter cabs, forty of them being Renaults and the other ten Berliets. In addition to the two garages they have stands at the Sherman House and the Illinois Athletic Club, where cars are continually held for hire. They aim to keep enough cars at each stand to meet the demand for same. As a car leaves the stand the fact is telephoned to the main office. and another cab is sent to replace it, the one that has been used either returning to the North or South Side office when dismissed, or if in the vicinity of the stand it returns there, the idea being to cut down dead mileage as far as possible.

About 50 per cent. of these cars are equipped with Stepney spare wheels, the rest are fitted with Fisk demountable rims, and it is the intention of the company to equip all new cars with the latter. That the number of cars will be increased is an assured fact, but no definite information could be obtained as to the number or make of new cars to put in the service. Franco-American taximeters are in use, and are attached to the rear wheels: The drivers of the cars receive both a salary and a commission. The company furnish all supplies and make all repairs, etc. No special agreement is in force between the manufacturers and this company as to maintenance. Tires are purchased on a guaranteed mileage basis. As a rule the busiest hours are from 5 to 7 p. m., when cabs are in demand by those dining out, and between 8 and 9 p. m. and 11 and 12 p. m. by the theatregoers. The cabs are much in demand on rainy days, as well as on the occasion of sudden showers, which catch the shoopers downtown without protection from the elements. The same charge is made for either one or four passengers, the rates being as follows:

For first mile	\$o . 50
For each quarter mile the	reafter
For each six minutes' wai	ting
For one hour's continuous	service 4.00
For four hours' continuou	s service 14.00
For five hours' continuous	service 17.00
For six hours' continuous	service 20.00
For every hour in excess	of six hours 2.50

There is no extra charge made for baggage carried inside the cab, but a charge of 20 cents is made for each piece of baggage carried on the outside of the cab.

To illustrate how the taximeter cab has grown in popularity in Chicago it might be well to state that this company have been in existence just one year. In the summer of 1908 they began with nine cabs; they gradually increased the number of cabs until now they are operating fifty, and they will continue to add to the number.

THE WALDEN W. SHAW AUTO LIVERY COM-PANY,

located at Twenty-first street and Michigan avenue, occupy a three story brick and concrete building, covering a space 60x130 feet. The two lower floors are used as relestoom and garage, and the upper floor

as repair shop. This concern was organized in October, 1908, and began business with twenty-four touring cars and two taximeter cabs. At the present time they are operating twenty-five Thomas taximeter cabs and six Atlas taximeter cabs, in addition to a number of touring cars, which latter are rented by the hour only. Thirty Jewel-Keating taximeter cabs for the exclusive use of Chicago's new hotel, "The La Salle," are under construction, and it is safe to say that before the expiration of the present year this company will be operating not less than 100 taximeter cabs. This firm is referred to as the "Contract Company," the reason being that they have contracts with the majority of the hotels and clubs to furnish cabs. It is claimed that the average gross earnings of the cabs in use are \$27 a day. The average mileage of each car is approximately 700 miles a week. Drivers are paid on a commission basis, they receiving 20 per cent. of the gross earnings. The management of this concern claim that the drivers working on a commission basis give better service to patrons than those receiving a salary. They contend that the man working on commission strives to please the patron so as to hold him as a regular, and, further, that as all of their drivers are competent and well versed in the operation of the automobile, such a thing as abusing a car is unknown with them. Extreme precautions are taken to prevent the overcharging of passengers. All drivers are under a cash bond, which is held thirty days after dismissal, and this bond is held as a sword over the head of the driver and practically forces him to be honest, both with the firm and its patrons. Drunkenness or dishonesty is met with instant dismissal, and in case of dishonesty prosecution is sure to follow. Gasoline, oil and repairs are paid for by the company. Jones taximeters are used and are operated from the left front wheel. For the purpose of checking the mileage shown by the taximeter Veeder odometers are attached to the right front wheel. This makes it impossible for the drivers to falsify the mileage records. An accurate account has been kept as to the average number of passengers carried per trip, and it has been found that but 17 per cent. of the loads exceed two persons. hence the rates are the same for either one or four passengers. In their touring car and limousine service the rates of hire are: For one or five passengers, inclusive, per hour \$5; for each additional passenger, extra, per hour, \$1. Time is computed from the moment the car leaves the garage until it returns. The taxicab rates are as follows:

For each quarter mile thereafter ... 30 cents
For each six minutes of waiting ... 10 cents

No charge is made for calls provided the customer rides as far as the car had to travel to reach him. The hourly rate is the same as that shown in the table of the Auto Taxicab Company. All cabs are

equipped with Fisk demountables, and a mileage contract exists between the company and the tire manufacturers.

CHICAGO TAXICAB COMPANY.

The largest concern in the taximeter cab business in Chicago at this time is the Chicago Taxicab Company, with a main office at 1322-24-26 Michigan avenue. This company has been organized only recently. It is incorporated under the State laws of Illinois, with a capital stock of \$500,000. It is an amalgamation of several companies formerly operating in a small way, including the Dan. Canary Taxi-Livery Company, Chicago Auto Livery Company. Kenwood Taxicab Company and the taxicab department of C. A. Cov Auto Livery Company. The officers of the new concern are Alderman A. B. McCoid, president; J. S. Kestner, of the Fair Department Store, vice president; Fred R. Upham, secretary; John R. Thompson, treasurer of Cook County, treasurer, and Dan Canary, general manager. In addition to their main office and garage they maintain various offices and stations scattered in the more thickly populated districts of the city where possible patrons reside. They are operating seventy Thomas taxicabs, nine Atlas taxicabs, and three White steamers, with taximeters attached. In addition to these they also have twenty seven-passenger touring cars of various makes, which are rented only at a flat hourly rate. The rates of hire for taxicabs are the same as those shown for the preceding companies. In addition to their various hacking stands, they keep a few "cruising" cabs." These continuously "float" around the downtown streets, especially during the evening, looking for fares. While they are "cruising" the "vacant" sign on the taximeter stands upright. This idea of course is a survival of horse cab days.

Mr. Canary states that Chicago will eventually have the most perfect taximeter cab service in the country. At the present moment he is working on a system by which the main office will practically be able to tell the whereabouts of any cab in their service, whether engaged or disengaged, at any hour of the day or night. He has promised a description when this system is perfected. The cars now in service are equipped with Jones taximeters which are attached to the front wheels. Some few of the cars carry Stepney spare wheels, but the greater majority carry Fisk demountable rims. It is the intention of the company to increase its number of cabs in the very near future, negotiations at present being under way for 100 new cars. These are not as yet contracted for, but the company are considering bids from several concerns relative to them.

The drivers are hired on a commission basis, the company furnishing oil, gasoline, etc., and a strict adherence to the rule of avoiding liquor when on duty is enforced.

In addition to the companies mentioned in this article there are several smaller

.

concerns operating from two to a dozen cars, and maintaining various stands at prominent corners of the city. The rates charged for hire are uniform with those charged by the larger companies, and as a rale the drivers work on a commission

#### AUTO LIVERY COMPANIES.

Following is a list of the companies doing an auto livery business in Chicago: tony Auto Surrey Company, 1710 Indiana avenue. ( W. Motley, 344 Michigan avenue, Was Pay-More Auto Livery, 205 East Twenty-

eighth street.

Adlake Auto Livery, 5039 Cottage Grove avenue. Auto Taxicab Company, 2441 Michigan avenue. Central Auto Livery, corner Jackson boulevard and Franklin street.

Central Garage Auto Livery, 276 East Fortieth street.

Colonial Auto Livery, 50 East Thirty-ninth street. Erwin Greer, 2213 Cottage Grove avenue. Huguelet Brothers, 204 Lincoln Park boulevard. Walden W. Shaw Auto Livery Company, Twenty-

first street and Michigan avenue. C. W. Miller Auto Livery Company, 418 East Superior street.

H. G. McGaughy, 67 East Eighteenth street. Owen H. Fay Livery Company, 53 Plymouth place. W. M. Traut, 243 Michigan avenue. Chicago Taxicab Company, 1322 Michigan avenue.

> Motorcyclists' Meeting at Indianapolis.

About 500 motorcyclists from all parts of the country attended the convention and meet of the Federation of American Motorcyclists at Indianarolis August 10-16. Preliminary to the convention there was an endurance run from Cleveland, Ohio, to Indianapolis, a distance of 362 miles, and the closing two days, Saturday and Monday, included races at the Indianapolis Motor Speedway.

There were ninety-six entries in the endurance run, of which sixty-five finished with perfect time scores and thirty-eight with perfect technical scores. The first day's run was from Cleveland to Columbus, via Coshocton and Newark, and the second day's run from Columbus to Indianapolis, via Dayton, Richmond and Conpersville.

On the second afternoon of the run there was a hill climb at Connersville, in which seventy-two negotiated the hill without penalizations.

1 motorcycle parade on Thursday afternoon and short runs to places of interest in Indianapolis and vicinity formed the principal features of the program. The Indiana Motorcycle Club kept open house at its clubhouse for the visiting riders.

#### New Body Building Concern.

The Glascock Brothers Manufacturing Company, Muncie, Ind., have recently started work on a brick addition to their factory on Fifth street and Perkins avenue, and upon its completion will take up the manufacture of automobile bodies. W. L. Cortelyou, an expert body builder, has been engaged as superintendent of the new department. It hopes to begin operation October 1. The company is capitalized at \$130,000, and John J. Dow is president.

#### Notes on Lubricating Oils.

(Presented by Frank H. Floyd, of Detroit, Mich., to the Society of Automobile Engineers.)

The important points respecting the use of oils are as follows:

That your cars are all carefully tested before placing them in the hands of the purchaser, and are in first class working shape.

That it is well to exercise careful judgment in purchasing oils, for their lubrication, that the wear and tear may be prevented.

That oils are usually sold under brands. and mean nothing.

That it is the property tests of an oil that determine its value as a lubricant.

That in analyzing numerous brands of oil on the American market the writer finds that they are strictly hydrocarbon oils, fractional distillates of crude petroleum, but of various specifications.

Fractional distillates are the different portions that are evaporated from crude petroleum by the refiner.

Gasoline, from 68 to 87 gravity; naphtha, 58 to 60 gravity; kerosene, 46 to 48 gravity; miners' oils, 38 to 49 gravity; light lubricating, 33 to 35; medium heavy, 22 to 31; heavy oils, 18 to 27 gravity, are fractions. True, oils are treated, filtered, etc., but in the rough they are parts of the crude.

That crude petroleum from different States, different wells, produces lubricating oil of entirely different properties under the same methods of refining. There is a choice.

That hydrocarbon oils employed in gas engine lubrication are by nature composed of hydrogen and carbon.

That the weight of oil is controlled largely by the amount of carbon in composition. That in practice the heat generated in gas engine cylinders is sufficient to cause all oils to evaporate and burn to a greater or less extent.

That in evaporating and burning the hydrogen is driven off by the heat, leaving the carbon to precipitate or pass off with the exhaust.

That there are no oils that will not deposit carbon when they burn, and no oils that will stand the high temperature at the point of explosion without burning.

That water and air cooling keeps the temperature of the metals down to a practical lubricating basis.

That oils of light weight (high gravity) contain less carbon in composition than oils of low gravity (heavy weight) and with deposit less when they burn.

That the evaporative or flash test, and the burn test of an oil is important to consider in conjunction with gravity.

That high, evaporative test and light weight oils will be less affected by the cylinder heat and will deposit less carbon when they burn. The desideratum.

That the viscosity or body test of an oil should be considered in transmission and in lubricating journals and shafting in the crank case, but in cylinder lubrication it is impossible to refine high gravity, high evaporative test oils with little body.

If both are high the body test will take care of itself.

That high grade gas engine oils are filtered to lessen the carbon and the gravity is raised, and the weight reduced as well as the viscosity, but the fire test is not affected.

That the various colors of oil are due to the bleaching effect of the filtering medium.

That color alone is not an index in determining a good gas engine oil.

That the cold or fluid test is important to consider at low temperatures.

That manufacturers will do well to regulate the temperature of oil in the receiver to get a uniform flow in all seasons, and not necessitate a change in the specifications of the oil.

That, finally, a good gas engine oil is one of high gravity (light weight), with a maximum high evaporative test, and a fluid oil at low temperatures.

That there are limitations in refining oils from high grade crude.

That you should consider all of the property tests of an oil in purchasing and not pick out one as an index.

I think the above covers much that can be said about gas engine oils.

#### Oakland Fours to Be Made in Jackson, Mich.

It is reported from Jackson, Mich., that the old Buick plant in that city will shortly house the factory for Oakland cars, which are now controlled by the General Motors Company. After the plant had been idle for some time a force of men was set to work several months ago to renovate it, and then several hundred tool makers were put to work in the plant making tools for the different General Motors factories. The tool makers will vacate the building by August 18, after which, it is said, the necessary machinery for the manufacture of the four cylinder Oakland cars will be installed.

#### Made to Suffer for Sins of Predecessors.

The Brush Chicago Motor Company has protested against a ruling of Chairman Chas. P. Root of the Chicago Motor Club contest committee barring the Brush from the Algonquin Hill Climb because of the advertising done by the Chicago Brush agents after last year's Algonquin contest. The Brush Chicago Motor Company were established in February last, and they claim they should not be held responsible for the acts of a former agent. The manager of the agency states that the manufacturers in all their advertising stated that the Brush had won in its class, and not that it had won the hill climb.

The date for the Olympia (London) Show has now been set for November 12-20. The annual dinner of the Society of Motor Manufacturers and Traders will take place November 10.

## NEW VEHICLES

#### Knox 1910 Models.

The 1910 line of the Knox Automobile Company, of Springfield, Mass., will consist of three models, as follows:

Model R, four cylinder, 40 horse power. Model M, four cylinder, 48 horse power. Model S, six cylinder, 57 horse power.

These ratings are based on the A. L. A. M. formula. All of the cars follow the same general line of construction as previous Knox models, and are provided with any of a number of different styles of bodies, including five and seven passenger touring cars, tourabout or close coupled bodies, tonneauettes, single or double rumble sportabouts, raceabouts, limousines and landaulets.

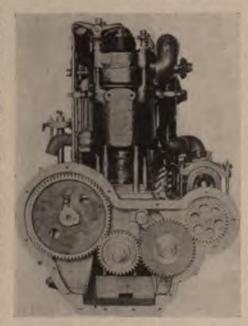

The Knox cylinder construction remains the same as it has been during the past two years; that is, the cylinders and cylinder heads are cast separately, each with its own water jacket, and are bolted together without water spaces at the joint, the jackets of the cylinders and heads being placed in communication by outside connections. The Model R cylinders are of 5 inch bore and 434 inch stroke, and the Model M cylinders of 51/2 inch bore and stroke each. All of the cylinders are cast separately, and a copper-asbestos gasket is placed between the cylinder and the head. One advantage of the separate head construction is that the combustion chamber may be machined all over, which makes it possible to secure absolutely equal compression spaces in each cylinder, and in addition gives a smooth surface, to which carbon will not stick as fast as to the ordinary rough casting. The water jacket of the head is cast with a division, making two chambers, so as to insure positive circulation directly over the valve seats. The U connection between the cylinder and head jackets is held in place by a double clamp and single bolt.

The Knox Company are now using flat head valves in all their motors, all of the valves being located in the head and operated mechanically by rockers and push

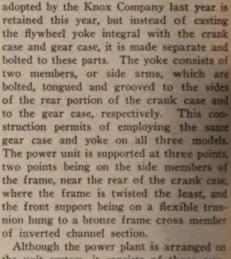

KNOX MODEL R.

rods. The upper ends of the push rods are in the form of hardened, cup shaped sockets, and screw in the ends of the rods for adjustment of the clearance. They are securely fastened by lock nuts, and the outer ends of the rockers with which they en-

FRONT VIEW OF MOTOR.

gage are ball shaped. These sockets are oiled to prevent wear. Spiral springs are provided for taking up lost motion in the valve mechanism, and thus insure quiet operation.

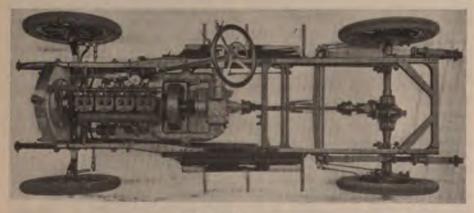

The unit power plant construction

Although the power plant is arranged on the unit system, it consists of three separate parts, any one of which can be removed without disturbing the others. The whole power plant can be taken from the chassis by taking out four bolts and uncoupling the forward universal joint, the muffler pipe, the ignition wires and the throttle and brake connections.

The crank case consists of four aluminum castings, the case proper, the bottom or base, and the timing gear case and cover. The case proper has a massive extension cast on at each side at the rear, which when finished makes one part of the forward joint of the yoke. This part supports all of the crank shaft bearings. The bottom of the case acts mainly as an oil reservoir, and is easily removed. The crank shaft and connecting rod bearings are lined with Parsons white brass, which is claimed not to injure the shaft in case of lack of lubrication. The connecting rods are drop forged from nickel steel, and have their heads fastened with four bolts, with contracting double lock nuts. The four bolts are said to make it impossible for the bearings to wear more on the ends than in the centre.

The Stromberg automatic carburetor is used. Ignition on Models M and R is by Bosch high tension magneto, and by battery, vibrating coil and timer, making two complete systems with two sets of plugs. The magneto is driven by enclosed gearing from the cam gears, and the battery

PLAN OF CHASSIS.

by spiral gears from the oil pump

cooling water is circulated by a cenal pump, which can be easily removed. drive is through a special spring conn, which will snap in case the pump d freeze up or be blocked in any other The pump can be completely drained. water is delivered from the pump gh a tapering manifold to the lower of each cylinder jacket; it passes out upper end of the jacket through the le connecter into the lower chamber e head, thence to the upper chamber out of the right side, through the remanifold to the top of the cellular radi-

SECTION OF REAR AXLE.

tem, located on the dashboard, shows at all times the pressure of circulation, which can be varied by means of an adjustable spring by-pass located on the left side of the motor. It is claimed that with this system of lubrication I gallon of oil will last for over 500 miles of ordinary running.

The power plant is slightly inclined downwardly toward the rear, so as to obtain a straight line drive. A new type, three speed selective change gear is used on Models R and S. The shafts and gears are made of nickel steel, and mounted on Hess-Bright and F. & S. imported ball bearings. The gear is very compact, the short shaft being only 5 inches between bearings. A change gear clutch is provided to prevent clashing of the gears in shifting.

The rear axle is of the semi-floating type, constructed so the shafts can be removed without dismounting the axle. The shafts are of 11/2 inch nickel steel, and a bevel gear differential is used. The rear axle is equipped with New Departure double race ball bearings, which take care equally of radial loads and side thrust, Four double race bearings are used on the rear axle, and two in the pinion housing. The front axle is an I section drop forging, with Elliott type steering heads, and with Timken roller bearings at the upper end of the pivot. The steering knuckle consists of drop forged and hand forged parts of nickel steel, the axle stubs being fitted with Timken roller bearings.

A new type of steering gear is used, of

the irreversible type, comprising a double screw motion with a rocker action at the base, which works the steering lever. lever and its shaft are of nickel steel. The spark and throttle levers are located on top of the 18 inch steering wheel. The brake drums secured to the rear wheels are pressed from one piece of sheet steel with an air space between the outer and inner rim to avoid any possibility of either brake dragging as a result of the expansion of the rim due to heat generated by the action of the other brake. The service brake is of the contracting band type; it acts on the outside of the outer rim and is pedal operated. The band is so fastened that it is freed of the rim, when not applied, by springs and a binder post. It can be adjusted by means of a very accessible turnbuckle. The emergency brake is applied by pulling back on a hand lever. It is of the expanding type, operates on the inner rim of the brake drum and can be easily adjusted. Both brakes are lined with Thermoid and are provided with equalizers.

The Knox Automobile Company make all of their vehicle bodies in their own factory. All open bodies are made of steel and aluminum, with a wooden base. They also make all their tops and their folding glass

The frames are made of cold pressed alloy steel, heat treated. Besides the bronze support which carries the trunnion at the front of the power plant, and the two rear points of support on the yoke, two pressed

SIDE ELEVATION OF KNOX MODEL R CHASSIS.

CHASE SURREY.

steel cross members are used. The frame has a 1½ inch drop at the rear and is inswept at the forward end to increase the steering lock. On the Model R 40 inch semi-elliptic front springs are used and 50 inch three-quarter scroll elliptic rear springs, with oil cups on all hangers and pins. All springs are of nickel steel. The wheels are 36 inches in diameter, and fitted with 4 inch Fisk bolted on tires on demountable rims. The car is stated to weigh 3,000 pounds with equipment.

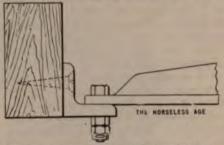

The Chase Surrey.

The Chase Motor Truck Company, of Syracuse, N. Y., have recently brought out a new design of car, a surrey which can be converted into a commercial runabout for the use of tradesmen, for light delivery, etc. The car is equipped with 40 inch wheels, fitted with 134 inch Firestone flat tread solid rubber tires It has a wheel base of 96 inches and weighs 1,400 pounds complete.

The motor is a three cylinder, two cycle vertical one, cooled by the Chase system of air cooling. A sectional view through one of the cylinders is shown herewith. It will be observed that the motor is of the three port type, with pre-compression in the crank case. The crank chamber is made of two iron castings bolted together in a horizontal plane through the centre of the crank shaft. The four main bearings of the crank shaft are exceptionally long and are bronze bushed. Counterweights are fitted to all of the crank arms, and the motor is thoroughly balanced.

The cylinders are of 41/8 inches bore and stroke respectively, and the motor is rated at 18 to 20 horse power. The arrangement of the ports is the same as in a conventional three port engine, except that the transfer passage is con tained entirely within the cylinder casting, and opens into the crank chamber through ports in the cylinder wall and the piston wall. This reduces the length of the passage, and should reduce the resistance encountered by the charge in passing from the crank chamber to the cylinder. The top of the piston is slanted downward from the upper edge of the deflector plate. Light drop forged connecting rods are used, and hollow wrist

pins. The cylinders are cast with annular flanges on their side walls and vertical flanges on the head. The flywheel is developed in the form of a centrifugal fan, resembling a paddle wheel in general appearance. The action of the flywheel is to draw air into the bonnet

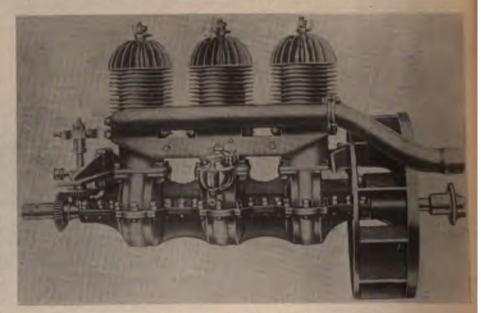

SECTIONAL SKETCH OF CHASE FRAME, (Not to scale.)

space, which is open in front, and over the cylinders, and to force it out around its circumference. A dustpan underneath the engine, conforming to the circumference of the flywheel, renders the air circulation more effective.

A Holley carburetor is used, and connects through a cast iron manifold with the crank case inlet ports of the three cylinders. Fuel is carried in a to gallon tank in the front seat, and is fed to the carburetor by gravity. The Atwater Kent unisparker is employed for ignition The make and break device is carried on a vertical shaft in front of the motor, and is driven by mitre gears from the crank shaft, and the coil is secured to the dash board. The current for ignition is furnished by a dry cell battery. Only a smgle set of cells is carried, which furnish current for 500 to 700 miles. The oiling system of the engine is exceedingly simple. There are no oilers or oil cups of any kind on the engine, except one grease cup on the timer shaft, all wearing parts being lubricated by oil mixed with the gasoline before it is poured into the tank However, each of the main crank shah bearings is provided with an oil tube for emergency lubrication by means of a squirt gun. These tubes are closed by spring pressed steel balls. It is the cutom to mix 1 quart of oil with every 5 gallons of gasoline. This lubricating system is said to have proven particularly satisfactory in connection with delivery wagons of small tradesmen, which are often operated by apprentices. It is impossible to either adjust the lubrication improperly or to entirely forget turning the oil on. The amount of lubricant used is in exact proportion to the work done by the engine, and there is therefore no possibility of excess lubrication, with its attendant sooting of plugs and foul ex-

Directly back of the engine is located a single universal joint, from which a driving shaft extends to the encased planetary change speed gear, which is built in one unit with the bevel gear and differential on the countershaft. The change gear gives two forward speeds and one reverse, and is of the conventional type with fibre disc high speed clutch and bronze low speed and reverse brakes. The countershaft is mounted in Hyatt roller bearings. The bevel gears

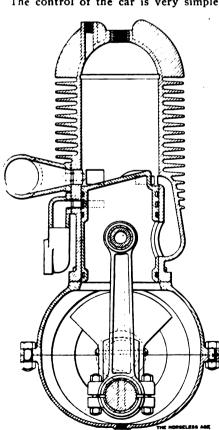

CHASE THREE CYLINDER, TWO CYCLE, AIR COOLED MOTOR.

on the countershaft give a reduction of 3 to 1, being cut with sixteen and forty eight teeth, respectively. From the countershaft the power is transmitted to the rear wheels by side chains running on sprockets of nineteen and forty-eight teeth, respectively. The countershaft bearings are held in the proper relation to the rear axle by means of adjustable distance rods. Both the front and rear axle are 13% inch square solid axles. The front axle is dropped in the centre. The car is carried on full elliptic springs in front and rear, which are clipped to the underside of the axle. The axles are of Sheldon make and equipped with Em pire ball bearings. The steering heads are of the Elliott type, and standard drop forged steering connections are used with ball and socket joints. The steering gear is of Barnes make.

For braking the car recourse may be had to the reverse gear, and in addition a set of Raymond brakes are fitted to the rear wheels. The brake drums are combined with the sprocket wheels, and are clamped to the wheel spokes by means of clips. The frame is of ash, the side members being sawed out to arch slightly upward, so as to prevent downward curving when the car is loaded. The ash sills are reinforced with angle iron members on the inside and flush with the lower edge, on which the mechanism of the car is supported. The engine is supported by means of two malleable iron cross beams, as shown in the side view of the engine.

The control of the car is very simple.

SECTION THROUGH CYLINDER.

CHASE DELIVERY WAGON USED BY NEW YORK CLOTHING HOUSE.

The steering post and hand wheel are located in the usual position on the right hand side. At the base of the post there are two pedals, the left hand one giving the low speed ahead, and the right hand one serving to apply the rear wheel brakes. The side lever gives the high forward and the reverse. The thumb levers for the spark and throttle are mounted on top of the steering columns.

#### The Lion Peugeot Two Cylinder Motor.

Recent tendencies in French motor design for small cars are well illustrated by the Lion Peugeot two cylinder motor, of 3 inch bore by 6 inch stroke. This motor has been designed to permit of being substituted for the single cylinder motors with which the company formerly fitted its light cars, as well as to be fitted to new runabouts. The two cylinders are arranged to make an angle of 20 degrees with each other. Both connecting rods act on the same crank pin. The motor has a built up crank shaft and enclosed flywheels. The long stroke necessitates flywheels of considerable size, and, in consequence, the crank case is of large diameter. One of the main engine journals carries at its outer end the male member of a conical friction clutch, and the other main journal carries the cam gear pinion. The cam shaft is opcrated through the intermediary of one set of bevel gears and one set of spur gears. The push rods are operated through the intermediary of bell cranks. The cam gearing is entirely enclosed so as to minimize the noise. The gear wheel keyed to the cam shaft meshes with a gear which drives the water and oil circulation pumps and the magneto. All of these parts are very accessible.

#### The Thomas 1910 Model "M."

The E. R. Thomas Motor Company, of Buffalo, N. Y., offer for the 1910 season a six cylinder, 40 horse power car, known as their Model M, which, with a very complete equipment, sells for \$3,500. The equipment includes a top, glass front, speedometer, horn, headlights, Prest-O-Lite tank, two oil side lights, a tail light and two complete ignition systems. The car is furnished with six different bodies, viz., touring car, runabout, tourabout, flyabout, landaulette and limousine. The bodies are of hand hammered aluminum and are luxuriously upholstered in leather and curled hair. The touring car seats five passengers. The car has a wheel base of 125 inches and standard tread.

The motor has a bore of 41/2 inches and a stroke of 51/2 inches, and is designated by the manufacturers as a long stroke motor. All of the valve ports and passages are exceedingly large and direct, the actual clear diameter of the passage carrying the gases to the cylinder being 21/8 inches, or one-half the cylinder bore. The valve measures 256 inches across the head. The valve seats and valve guides are completely water jacketed so as to allow of continuous running under load without local overheating.

The pistons are 51/2 inches long and are provided with four narrow rings. The connecting rod is 113/4 inches long, three-quarters of an inch longer than twice the stroke of the motor. The crank shaft is 17% inches in diameter, and has a total projected area of 52.6 square inches. The cam shaft also has a very liberal bearing surface, and the bearings are located very close to the cams. The total projected area of the bearings of each shaft is 11.3 square inches. All the bearings of the motor are plain, the crank shaft main bearings and crank pin

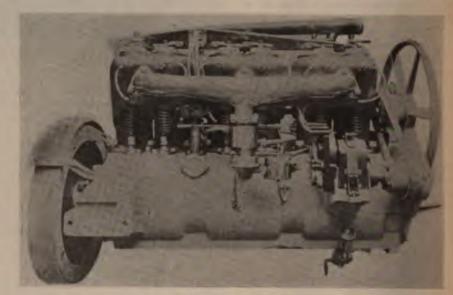

THOMAS MODEL M SIX CYLINDER, FORTY HORSE POWER TOURING CAR.

bearings being bushed with die cast babbitt bushings, which are easily renewed, since they are interchangeable. The cam shaft bearings are of bronze. The crank shaft is a carbon steel drop forging, heat treated. The connecting rods are of 3½ per cent. nickel steel. The cam shafts are also of nickel steel, as are the connecting rod bolts. The flywheel, instead of being an iron casting, as in the majority of cars, is cast of steel, and an accident due to racing of the motor is therefore impossible.

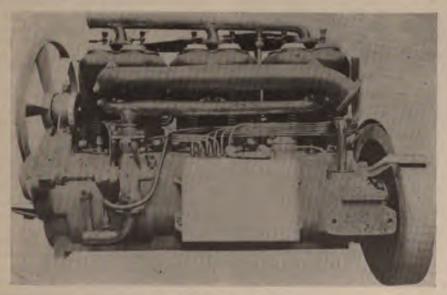

Particular effort has been made in designing the motor to insure quiet running. Thus, the cam gears are made of the herringbone type, of steel and phosphor bronze, respectively; the valve plungers have been provided with fibre inserts, and the clearance of the valve stem bearings has been reduced about 50 per cent. In order to insure absolute balance the pistons of all the cylinders are standardized in weight, all revolving parts are carefully balanced, and the compression spaces of all the cylinders are equalized.

The Thomas three disc clutch, used on former models, is retained on the Model M. The clutch disc is carried on two imported annular ball bearings, so a scarcity of lubricant will not cause dragging. Two universal joints of the internal gear type are inserted between the clutch and the change gear. It is stated that this type of universal joint has given entire satisfaction in service on motor trucks where all other forms of joints failed. The clutch is provided with cork inserts and has a double adjustment. By cranking the cross shaft of the clutch mechanism the clutch has been made much easier to operate. The change gear weighs complete only 82

The change gear weighs complete only & pounds, and is equipped throughout with imported annular bearings. It was designed to secure very short shafts, so as to be very rigid. The distance from centre to centre of the annular ball bearings on the countershaft is only & inches. Six annular bearings are used in the gear box. The gears

INLET SIDE OF MOTOR.

EXHAUST SIDE OF MOTOR

are nickel steel, case hardened, the case hardening process consisting in carbonizing in powdered bone, allowing to cool in the pot, reheating to between 1,375 and 1,425 degrees, and finally quenching in oil.

The rear axle is a Timken axle, with pressed steel casing and Timken roller bearings throughout. The bevel gears are of four pitch and give a speed reduction of 3 to 1. The company state that they tried out one of these axles on a heavy car of greater horse power without discovering any signs of weakness. The front axle, 25 well as the steering knuckles, are made of nickel steel. The springs are of alloy steel.

The ignition is effected by a Bosch DR-6 magneto, which furnishes current to one set of plugs, and an Atwater Kent unisparker, which supplies the second set of plugs. The engine piping is of drawn copper tubing, and is consequently quite light. Among the improved details on the new model may be mentioned the ball and

socket joints in the magneto and carburetor control mechanism, which is very closely adjustable. The wiring is carried in carefully designed housings. The fenders and running board apron absolutely protect the passengers against splashing mud.

## Eisemann High Tension Dual Igni-

tion System.
This system is designed to fill the demand for a magneto system which permits of starting the motor from the seat. It comprises a Type E K magneto, a non-vibrator dash coil combined with a high and low tension switch. The make and break mechanism and the high tension distributor serve for both the magneto and the coil, and the distributor is positively connected to the make and break mechanism, so that both are advanced or retarded in unison, and the distributor arm is therefore making contact with a segment at all times when the make and break contacts are in the firing position. This feature and the formation of the laminated armature core, which is of the

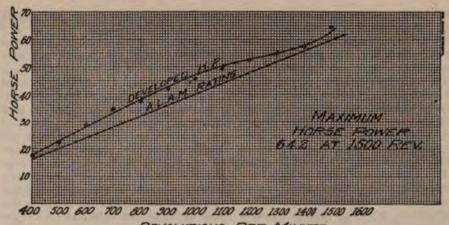

STARTING COIL.

modified H type, make the system particularly suitable for two cycle engines, because of the wide timing range of the magneto. The magnetic field is produced by two, three or four simple or double magnets, according to the size of the magneto. The pole pieces are of new design, the edges being cut along helicoidal lines instead of being straight. With this construction the armature is in touch with the pole pieces, or a greater portion of revolution than in former design, and the range of spark lag and lead will be greater on account of the more even field.

The armature is of the double T type. the central part being laminated. The primary winding is wound directly on the core of the armature, being insulated from the latter by several layers of high grade insulating silk, and the secondary winding is wound on the primary. One end of each winding is grounded, the other end from the primary is connected with the breaker, and that of the secondary with the slip ring or collector.

The starting coil includes a stationary induction coil with condenser for increas-

REVOLUTIONS PER MINUTE Horse Power Curve of Thomas Six-Forty Motor.

ing the voltage of the battery current and the switch which carries the high and the low tension currents at the same time. This switch is constructed of copper segments inserted in thick hard rubber, and is claimed to be perfectly proof against leaking and wearing.

#### The Palmer-Moore Low-High Speed Two Cycle Motor.

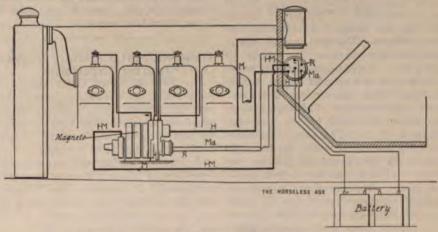

The Palmer-Moore Company, of Syracuse, N. Y., who have recently removed from 315 East Washington street to corner Tallman and Oneida streets, have had a patent allowed them on a new design of two cycle motor which they intend to develop for automobile purposes. The company have been manufacturing two cycle motors for marine work for a number of years, and the new motor is a development of their marine motor, the recent improvements enabling it to run at high speed and to develop proportionately more power.

A feature of the Palmer-Moore marine motor, and also of the new motor, is that the combustible charge is not compressed in the crank case, as in the majority of two cycle motors, but in a closed chamber underneath the piston. In the lower portion of the cylinder there is a smaller cylinder which acts as a crosshead guide. The working piston is connected to a piston rod which extends through a stuffing box in the head of the crosshead guide, and is fastened into a crosshead at its lower end.

This enables the company to get any desired amount of precompression. In the engines so far made the precompression is carried at 12 pounds per square inch. The marine motors are of the open base type, the cylinders being carried on four steel columns, as shown in the accompanying sectional sketch. The automobile motors are to be of similar construction, except that side plates will be provided for enclosing the

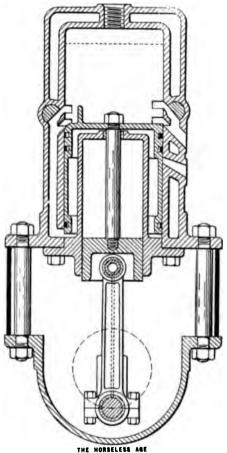

The engines are made in both a two port and a three port type. The novel feature of design above referred to consists in the provision of double transfer and exhaust ports. The two sets of ports are located one above the other, and are of the same width. The lower ports are of the same size and similarly located as those used in the slow speed marine motors, and when the engine is being operated at slow speed only these ports are effective, the upper ports being then closed by means of simple rotary valves.

The various valves are all connected together, and are held closed by means of a single spring and opened by means of a foot button. The valves consist of cold rolled steel pins of about I inch diameter placed in holes drilled into the cylinder castings, one side of the pins being flattened opposite the ports. The theory of the design is as follows: In order to enable a two cycle motor to run at high speed the ports must be much wider than they are

WIRING DIAGRAM OF EISEMANN DUAL IGNITION SYSTEM.

usually made on low speed, two cycle motors. At low speed, however, these wide ports are objectionable, because not only is the pressure in the cylinder during the down stroke of the piston relieved long before the piston reaches the end of its downward stroke, and thus power lost, but since the transfer port and exhaust port are open simultaneously for a much longer time than is necessary a considerable portion of the new charge is likely to leak out through the exhaust port before it closes. In fact, tests made with the object of determining the best port dimensions for high speed, two cycle engines have shown that increasing the port sizes usually increases the maximum power output, but it is not advisable to go beyond a certain point, be-

Section of Palmer-Moore Motor.

cause the fuel efficiency decreases as the power increases. Moreover, a high speed engine will not work at very low speed.

The Palmer-Moore Company are at present showing a two cylinder motor of 51/4 inch bore by 41/4 inch stroke, which they rate at 10 horse power. This engine, they state, will operate under load at from 200 to 1,300 r. p. m. They are at present using a mechanical lubricator, but later on expect to mix the oil with the gasoline for cylinder lubrication, and use oil bath lubrication in the crank chamber. As there is practically no possibility of the oil from the crank chamber getting into the cylinder in this type of motor, a very large amount of oil can be put into the crank chamber.

## New Factory for Frank Mossberg Company.

A \$50,000 factory is being erected for the Frank Mossberg Company, Attleboro, Mass., near the New York, New Haven & Hartford Railroad, a quarter mile south from the centre of the city. The building is erected with funds subscribed by local business men, and will become the property of the Frank Mossberg Company at the end of eight years, provided certain requirements are lived up to. It is to be completed by December 1. In addition to the main building, which is to be a brick structure 290x60 feet and two stories high, a power plant will be erected. The main floor of the main building will be used for the presses and heavy machinery, while the second floor will be used for light manufacturing, tool making, etc.

## Jewel Motor Car Company Reorganized.

A complete reorganization of the Jewel Motor Car Company, of Massillon, Ohio, has been effected by H. A. Croxton and J. M. Keeton. The name of the concern has been changed to the Croxton-Keeton Motor Company, and the capitalization increased from \$250,000 to \$500,000. H. A. Croxton, the new president, is a leading spirit in the iron and steel business in Massillon, and J. M. Keeton was formerly connected with the Pope-Toledo and De Luxe concerns. Plans are under way for a large addition to the plant, and an option on 7 acres of additional ground has been taken. The capacity of the plant has been doubled. Distributing agencies have been opened at New York, Cleveland, Pittsburg and Boston.

## Women Complete Transcontinental Trip.

Mrs. John R. Ramsey, of Hackensack, N. J., and associates, who started from New York a little over a month ago on a transcontinental trip in a Maxwell touring car, arrived in San Francisco on August 6, after being thirty-five days en route. The Maxwell-Briscoe Motor Car Company state that this is the first transcontinental trip made in a motor car by a woman. Mrs. Ramsey was accompanied by Mrs. N. R. Powell, Mrs. W. Edward and Miss H. Jahns, all of Hackensack, N. J.

Transcontinental Military Dispatch Bearing Experiment.

The Mitchell Motor Car Company, of Racine, Wis., last week shipped one of their new six cylinder, seven pasenger touring cars, 1910 model, to New York for use in the first transcontinental military dispatch bearing expedition ever attempted in the United States. The car will bear dispatches from General Leonard Wood at New York to General J. F. Weston at San Francisco. The car will carry five regular army officers and tents and camping outfits. A rapid fire rifle will be mounted on a special platform in front of the driver.

## Seismograph for Registering Motor Car Jolts.

At a recent soirée of the London Royal Society the Hon. R. C. Parsons exhibited a seismograph arranged to register the jolts of an automobile. The apparatus consists of a weight carried by the horizontal arm of a belt crank lever, the other arm of which is connected to a link holding a pencil against a paper covered revolving drum. Jolts displace vertically the point of suspension of the bell crank lever, giving an angular movement that is recorded by a horizontal motion of the pencil on the paper of the drum. The record gives an indication of the movements of the car body by obstacles or depressions in the road.

Hammondsport, N. Y., Motorcycle Concern Reorganized.

The Marvel Motorcycle Company has been organized at Hammondsport, N. Y., and has taken over the motorcycle business of the Motorcycle Equipment and Supply Company, which has been conducted by C. L. Waters for some years. Mr. Waters will be general maanger and C. P. Rudd superintendent. A building site has been bought and work will be immediately begun on a two story concrete block building 115x30 feet, which will be ready for occupancy by October 1. The company is incorporated with a capital stock of \$50,000.

Gary Company Absorbs Multi-Unit Engine Company.

The Gary Motor Car Company, of Muskegon, Mich., have taken over the factories, machinery and assets of the Multi-Unit Gas Engine Company, of Chicago. The Multi-Unit Company operated two factories, at Sheboygan Falls, Wis., and Connersville, Ind., respectively. The Multi-Unit engine will be used on the Gary vehicles. The officers of both companies are the same, and the transfer was made in consideration of an exchange of stock. It is said that the two plants will eventually be removed to Muskegon.

Separate Franklin Commercial Department.

The H. H. Franklin Manufacturing Company, Syracuse, N. Y., have established a special department for the manufacture of commercial cars. Herbert Hess is manager of this department, and W. F. Kneip is in charge of the engineering staff. A special building about a block away from the main factory of the company has recently been leased to house the commercial vehicle department and part of the sales department of the company.

Simplex Motor Car Company to Double Its Factory Capacity.

The Simplex Motor Car Company, of Mishawaka, Ind., are receiving bids on a single story brick building 72x240 feet, a duplicate of their present building. The contract will be let immediately.

#### COMMUNICATIONS

## Feeding Gasoline from Gravity Tanks on Steep Hills.

Editor Horseless Age:

I live among the foothills of the Adirondacks. It is a region where if you travel you must go either up hill or down. A motor car is never on the level save when on the bridge that spans the brook between the hills. I own and navigate the "most popular runabout." The fuel tank holds 8 gallons. It is never safe to go out with less than 5, and even then it is prudent to keep within sound of the dinner horn, for the frequent sharp, steep hills will leave your carburetor as dry as Sir Walter Scott's Reverend Doctor Dryasdust. Result: A halt as abrupt as a bucking broncho's, a jamming on of the "emergency," a blocking of front or rear wheels-both of them-a release of the low gear to see if the "most popular" will stand for cranking, a tickling of the inlet valve and getting no response, and, finally, a picturesque objurgation of the man who can make a car, sell it to the unsuspecting with a warrant that it carries fuel enough to take him 200 miles when in fact it will hang him up on the first steep pitch if his gasoline gets 3 gallons below the tank capacity.

For every ill there is a remedy. Having laid the foundation, let me apply it.

The screw cap to the tank has an ample flange. Fit a leather gasket under it and the tank becomes airtight under a low pressure. Drill and tap this cap for a one-eighth inch pipe plug. Drill a one-sixteenth inch vent hole through this plug. Take another plug, drill it so a common Schrader air valve will just wedge in snugly. Apply a little shellac varnish to the stem of this air valve to make it tight. I like this better than using a brass plug and soldering in the valve, for if the plug after it with a screwdriver, without jamming the valve case.

Now go out with your 5 gallons fear-lessly. Your vent plug is in place in the tank cap and your valve plug in your vest pocket. Get hung up on the first pitch and enjoy a sense of triumph as you search the surrounding country for a fence rail or two good sized stones to block your wheels with. Remove the vent plug from the cap, put the valve plug in its place. Serew on your air pump and three strokes will send the gasoline forward with a rush. Be gentle now; not too much pressure or you will flood things. Get in and ride to the top in ecstasy.

The only reason for a separate plug for the air valve is that the gasoline fumes will eat away the little rubber packing so it will not hold the pressure. Thus endeth the first lesson.

In 1851 a cute Yankee, Francis by name,

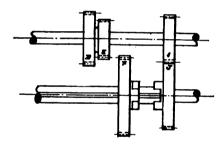

went over to the Crystal Palace Exhibition in London and showed the astute Britisher how to make a self baling lifeboat. The rocking of the boat raised the water inside of it and discharged it. Any motor car at speed rocks like a dory in a tempest. Is it beyond the capacity of the motor maker to make a tank that will elevate its contents so the final drop can be used? A word to the wise is sufficient. A word to the don'tcare-a-Vanderbilt for the man who gets hung up and is forced to carry 8 gallons when he can utilize but 5 (prairie countries excepted) is lost upon him. Let him alone. "His eyes is sot," as Governor Hoard used to say of the dying family horse. But the lifeboat man will come along, by and by, and his gasoline tank will have its contents where the gray matter of all manufacturers should be-in the upper story.

J. S. CORBIN.

#### Pressure on Gear Teeth.

Editor Horseless Age:

In your Engineering Number of November 7, 1906, on page 595, is an article on "The Factor of Safety in Transmission Gears," by Professor Rautenstraugh. In the first case considered (see Fig. 1), he assumes the torque of the shaft to be 2,000

inch pounds. From the formula given in "Machine Design," by Professor Unwin, page 214, viz., T=P. R. = 63,024  $\frac{H \cdot P \cdot}{N}$ , if we assume the revolutions per minute at 1,000, we find the horse power to be 31.7, or, say, 32.

Again, on page 328 of Unwin is this

formula for computing the tooth pressures, viz.,  $P = 63.020 = \frac{H.\ P.}{R.\ N.}$ . Where R = radius of gear in inches, N = revolutions per minute. This formula when applied to the two gears I and J gives for P = 781.5, which agrees fairly well with the professor. If you will kindly enlighten me how he gets P = 1,000, for gears E and F (see enclosed sketch), you will do me a great favor.

T. O.

[It is the squared shaft which transmits a torque of 2,000 pounds-inches, that is, a force or pressure of 2,000 pounds at a radius of 1 inch. The pinion A has a pitch radius of 1½ inches, and at this radius the pressure is evidently 2,000 + 1½ = 1,600, which agrees with the article. The pinion C has a pitch radius of 2.083 inches, and the pitch line pressure is therefore

2,000 + 2.083 = 960 pounds. The article gives the pressure as 1,000 pounds. The pinion F has a pitch radius of 2.25 inches, and the pitch line pressure would therefore be

2.000 + 2.25 = 888 pounds.

The article gives 1,000 pounds. It would seem that Professor Rautenstraugh had taken round figures all through, as all the loads on teeth are given in full hundreds of pounds; but the load on the teeth of gears E and F should have been 900 pounds, it would seem, instead of 1,000 pounds.

—ED.]

## Acceptance of Car for Bail. Editor Horseless Age:

If I am arrested for speeding, because my lights are out or my license is gone, do the police have to take the car as bail if I offer it? Cannot I 'phone a friend for bail? If the man driving the car goes with the officer, can the car be held? I mean should the police allow the above under the present law, not would they do it?

H. H. W.

[The New York State law is very definite in regard to the first question. Sub-division 3 of the law reads as follows: "Release from Custody, Bail, etc.-In case the owner of a motor vehicle shall be taken into custody because of a violation of any provision of this act, he shall be forthwith taken before an accessible captain or a sergeant or acting sergeant of police in any city or village, or any justice of the peace or magistrate, and be entitled to an immediate hearing; and if such hearing cannot then be had, be released from custody on giving a bond or undertaking executed by a fidelity or surety company organized under the laws of this State and having a deposit of at least \$200,000 with the Superintendent of Insurance of this State, said bond or undertaking to be in an amount not exceeding the maximum fine for the offense with which the owner is charged, and to be conditioned for the owner's appearance in answer for such violation at such time and place as shall then be indicated; or on giving his personal undertaking to appear in answer for such violation, at such time and place as shall then be indicated, secured by the deposit of a sum equal to the maximum fine for the offense with which he is charged, or in lieu thereof, by leaving the motor vehicle, being operated by such person, with such officer; or in case such officer is not accessible, be forthwith released from custody on giving his name and address to the officer making such arrest, and depositing with such officer a sum equal to the maximum fine for the offense for which such arrest is made, or in lieu thereof, by leaving the motor vehicle, being operated by such person, with such officer; provided, that in such case the officer making such arrest shall give a receipt in writing for such sum or vehicle, and notify such person to appear before the most accessible magistrate, naming him, on that or the following day, specifying the place and hour."

The automobile law thus provides that you

can either file a bail bond, put up cash bail, or leave your car as bail, and it would seem that everyone arrested should be able to furnish at least one of these different kinds of bail. The automobile law does not say anything about telephoning for bail. This is a matter that would come under the rules of the police department. It is the driver who is held for an offense, and if he accompanies the officer the car cannot be held.—ED.]

## Relative Balance of Different Engine Types.

Editor Horseless Age:

Will you kindly give, if possible, in the appropriate department of your valuable paper, the method of determining the relatively perfect balancing of vertical, horizontal and V type cylindered engines from one to six cylinders of each type? H. R. S.

[If we understand you correctly you want figures expressing the relative perfection of balance of the different types of engines. For instance, if the balance of the six cylinder type was put down at 100, that of the four cylinder type might be 75, or some such figure. We do not believe that it is possible to give such figures. We can, however, arrange the different engine types in the order of perfection of balance, as follows: 1, Two cylinder 90 degrees V, four cylinder opposed horizontal and six cylinder vertical, all perfectly balanced; 2, two cylinder opposed; 3, four cylinder vertical; 4. three cylinder vertical; 5, two cylinder vertical; 6, single cylinder vertical. This comparison is based on equal cylinder dimensions and not on engines of equal powers.—Ep.1

## Defective Piston Pin Design. Editor Horseless Age:

In your issue of July 21 is a scheme for fixing piston pins. I came across it in my scrap book last winter about the time I was doing over one of my cars, a 18-23 Mercedes, 1904. This car has to be done over every year, and the pistons had been drilled and tapped four times, necessitated in previous years by the Mercedes system

of fastening piston pins, with which you are probably acquainted.

Anyway, I suggested the idea to my mechanic, and we decided for the idea mentioned. I drew very carefully to full size the pistons and worked out the design to our needs, a photo of which design I enclose. This work was most beautifully done; you may take my word for this, as we have only high grade machines and tools.

The work finished, my machinist and I left my home at Nice and drove here (Les Sables d'Olonne), where we spend our summers. After about 1,500 kilometers a knock developed; we thought naturally the bronzes had gone. The cylinders were slipped off and we found that all four pins had broken at the taper pin hole, the cylinders were scored badly, and from the looks of the breaks we suppose the pins had broken the first day the motor was run. It was only good fitting that had held the pistons and connecting rods together.

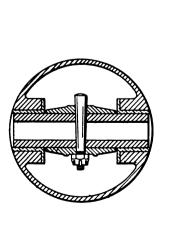

This experience of mine may not interest you at all; but if by chance it should, and you have any suggestion to make as to the possible cause of failure, I would be glad to have it. The steel used, while the best I could buy at Nice in a hurry, was not best quality cast steel. My stock of Sheffield steel was undersized. In the circular section of the piston pin you will see that I gave a taper of roughly 1 mm. in 36, this taper being the standard taper of taper pin reamers in France. As I say, it is only approximate. Maybe the taper pin was too big for this size piston pin. Maybe the cone or taper was too fine, and consequently "brutal." Maybe it was only the poor quality steel. Maybe only the bearing ends of the piston pin should have been hardened, leaving the taper pin hole annealed. W. H. B.

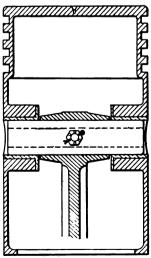

[It is really not surprising that the pins broke if they were of hardened steel. The hole for the pin in the centre will localize the bending strains at that point, and unless the pins were very large, as compared with the usual practice, they might be expected to snap off under the force of the explosion, the same as Mushet steel snaps off when notched on a grinder, clamped in a vise and dealt a light blow with a hammer. To remedy the defect we would suggest to bore out only the ends of the pin, leaving the central portion where the hole for the taper pin comes solid, and confine the hardening of the pin to the end bearing portions.—Ep.]

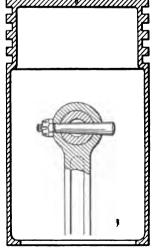

## Manufactured versus Assembled Cars.

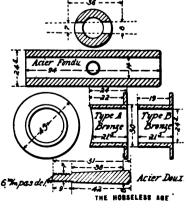

Editor Horseless Age:

For obvious reasons the question, or rather subject, of "manufactured" and "assembled" cars is of interest to the owners and prospective purchasers of motor cars. Technically speaking, every car is an assembled car; but what is of importance is whether the parts are fitted or merely "thrown together," as shabby work is termed in machine shop parlance. Aside from the question of suitable material. which is now selected from what past experience has proven best, and on which there are very reliable data as to method and ease of machining, as well as subsequent wearing qualities, care and discretion in treating, fitting and assembling, are the only guarantee against chronic trouble and satisfactory operation during the life of the car, provided the design is mechanically right and does not embody new and untried experiments. Simplicity of construction is also very desirable, and parts should be few in number and readily accessible. The demands made on a car are usually very severe, and running conditions often unfavorable, and this makes it all the more imperative that the small light weight parts should be correctly adjusted. While careful machining to the limits called for on drawings does not eliminate the work of the assembler nor constitute any excuse for carelessness on his part, it minimizes his work and makes for greater interchangeability in case of repairs. As the automobile is made up of so many different parts very few manufacturers possess sufficient space and equipment to do all the required machining, and are thus obliged to buy from

Working Drawing of Piston Pin and Piston.

others, made to their orders, parts which cannot be bought in the open market as standard material. Such parts are cast, drop forged, punched, bent and machined to blue print and pass a rigid inspection before being sent to the stock rooms. Complicated pieces which are hard to machine and must be perfect are more often let to part makers than pieces of less difficult shape, that can be readily finished on standard machines. When this is the case the jig and special tools used are the property of the manufacturer, which places him in position to furnish satisfactory repairs. Where these pieces are made from castings the patterns are, unless universally standard, the property of the manufacturer. The dies used in the making of drop forgings are owned by the drop forge men, but subject to the wishes of the manufacturers, so that repairs are available, even if such forgings are discarded on later models. The manufacturer (and there are many of him) who buys his parts, as outlined above, has the choice of his material; it is made up to his specifications, inspected and assembled at his own factory, and there can be no reason why a car so made is not the equal of any other car "built entirely in our own works," if his inspectors are up to the job and he is not pressed to use culls. As the use of parts not accurately machined means a loss to him in additional assembling expense, such defective parts are usually rejected, the parts maker standing the loss, which might not be so if the parts were machined in the manufacturer's own shon.

The manufacturer who buys all or some of his units, such as engines, transmissions, axles and clutches, relies almost entirely upon the honesty of the parts makers and the thoroughness of his final inspection, unless he tears down and reassembles. This adds to his assembling cost, but he has a direct knowledge of how workmanlike the parts have been assembled. It may also explain why two such manufacturers, using virtually the same units, have different selling prices, and that the higher priced one is able to guarantee his product while the other does not. It certainly is of interest to the manufacturer, as of subsequent benefit to the user, to have the advantage of more than a superficial inspection, and it may be well to remember that a finely finished exterior does not compensate for concealed defects. A piston not properly fitted to the cylinder means a knock, leaky piston rings, less efficiency, imperfectly seated valves. A crank shaft that is not perfectly balanced with its piston and connecting rod parts may eventually wreck the engine. Parallel shafts should run in true alignment; gears should run in mesh, neither binding nor running loose at different spots, which tends toward noise and excessive wear; the bearings should run free and allow for proper lubrication.

Water jacketed cylinders should be free from porous spots and cracks, and be thoroughly tested for sufficient periods of time. Engine bases, transmission cases, rear axle housings and other parts that contain oil should be well fitted and free from unsound spots to prevent leakage.

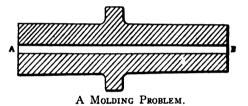

To sum up, a car that is well designed, made up of good, serviceable material, devoid of intricate mechanisms and attachments, which are usually trouble breeders, should give good satisfaction on the road, no matter where or by whom the parts have been machined, so long as the assembler's work has been well done, for it stands to reason that he is last and final in the long line of responsibilities involved in the manufacture of automobiles.

H. G. SCHWOEPPE.

#### A Molding Problem.

Editor Horseless Age:

I am experimenting with a substance intended as a substitute for the porcelain or mica cores of spark plugs. The composition is melted and poured into molds, but the difficulty is that it sticks to the plunger of the mold. The form I am trying to get is that used in the old Knox models and trucks (see enclosed sketch). A B is a

circular opening of about three-sixteenths of an inch diameter running through the length of the core. Can you aid me?

J. S. M.

[If the composition sticks quite fast to the core why not use the central pin or terminal of the spark plug for a core and make the central terminal and insulator in one? If this is impracticable for any reason, some form of destructible core must be used as in foundry work, but we do not know of any substance suitable for the purpose.—Ed.]

#### Comfortable Seats.

Editor Horseless Age:

It pleases me to see that somebody has started a discussion of so necessary a feature as the seats of the auto. Appearance rather than comfort has seemed to be the guide for building these in the past. I have been so placed for years that the output was limited, so I have not had any need to build to sell, and therefore have spent much time on features such as the securing of comfortable seats. High and low, long and short, with back vertical and much inclined, have been tried, not once but repeatedly. My conclusions, based on the verdicts of the users of these various seats in rigs practically alike as well as on use of them myself, is in favor of deep springs, a fairly level cushion and a back that is nearly vertical. This back should be so low that a rider can rest an arm on it when desired. Having deep springs, one can recline against the back with no fear of getting against hard supports; and the rig can rock over the water bars and gutters without transferring the motion to the rider. Further, the low back does not support the shoulder blades, but leaves the upper part of the spinal column free to follow the tossing of the vehicle. This is much more comfortable on the average American rough road than a back so high as to support the shoulders, because in that case the tossing must be taken by the neck, with the result that one's head is nearly jerked off at every water bar. I have known a woman to ride 60 miles in a popular touring car and then have to take to her bed for several days because of the intense pain in the back of the neck due to these jerks. And the shape of the touring car has been bad, because springs could not readily be fitted to the upholstering. The backs of many tonneau seats have very little more elasticity than a carpeted board. The inclined back and raised front cushion are splendid sellers. The buyer and his wife feel so cosy and comfortable when they drop into such a seat. But the first hard jolt tells another story. Mankind's internal mechanism is not rigidly anchored fore and aft. It will stand hard jolts in a direction parallel to the spinal column, but not crosswise thereto. The rider who can sit up and ride all day finds discomfort in a short while if partly reclining and jolted. At each jolt he unconsciously tries to resist, and this is tiresome. But I have found it impossible to make the buyer believe those things. He likes the riding of the rig, but wishes it was built so it looked like some of those big touring cars with hard upholstering as high as the shoulders and then turned over backward to make a good rest for his head. Buggy builders used to make comfortable backs, but since the auto set the style it is my opinion that there has been a decided loss in comfort. Lots of folks buy green fruit unfit to eat because it looks nice, and the auto buyer is no CHAS. E. DURYEA. exception.

## Loosening Refractory Nuts. Editor Horseless Age:

Will you kindly inform one of your readers whether in starting to unscrew a nut or bolt which is difficult to start there is any real or fancied advantage in turning it at first a slight amount in the wrong direction; that is, the direction which would tend to tighten it still more? Having seen several men doing this, I once asked one why he did it, supposing that he was momentarily confused as to the proper direction to turn the nut, and I was informed that it made the nut easier to remove. Not seeing the logic of this method, I have never cared to try it with a nut which was really difficult to remove, and I would like to ask you for information on this point.

W. S. D.

[Turning the nut the wrong way will certainly not help to loosen it if it is held only by mechanical pressure and not rusted in place, and would simply make it tighter.

However, if the nut is rusted, it is quite possible that turning it the wrong way will help to loosen it, as the reversal of the strain will help to break down the rust. Strains alternating in direction are very much harder on machine parts than strains always in the same direction, and the same should apply to the rust.-ED.]

#### Piston Pin Fastening.

Editor Horseless Age:

In a recent issue you mentioned a new method of fastening piston pins. The Crest people at one time used a design like that given below. The piston is slit for the cotter pin. I have used one of these mo tors as a stationary power plant for several years, and the above method works excellently.

[If we understand your sketch correctly, both the small pin and the split pin are lodged in slits or grooves on the outside of the piston. This method of retaining the pin is new to us and seems to be simple and dependable.-Ep.]

#### The Relative Seriousness of Ignition Trouble.

Editor Horseless Age:

On looking over your issue of August 11 we note your publication of a letter from the Maxwell-Briscoe Motor Company regarding the Glidden Tour. In one of the paragraphs of this communication it is stated that "ignition trouble is one of the most serious difficulties to the average automobilist, and one which is the cause of more stoppages than any other one thing," This statement is hardly fair, since it has been our experience that an automobile equipped with a first class magneto has no serious trouble whatever caused by ignition, and in the present almost universal use of the magneto the lack of attention it requires has led to complete forgetfulness of the ignition by the motorist.

In support of these statements it might be well to call the attention of your readers to the fact that of thirty starters in the Glidden Tour twenty-seven used magnetos. Of this number twenty-one were equipped with the Bosch, and we are happy to state that the tourists using this instrument went through the long grind without once touching the magneto for any adjustment or repair. We think that this is pretty good evidence that magneto ignition is the only practical system of perfect firing for internal combustion engines.

> BOSCH MAGNETO COMPANY, Otto Heins, Vice President.

Arthur E. Adams, manager of the Algonquin Motor Car Company, Boston, Mass., died at the Boothby Hospital, Boston, on August 12, at the age of twentyeight. Mr. Adams entered the automobile business as a salesman for the Pope Manufacturing Company, and was connected with one or two other Boston agencies before he became manager of the Algonquin Company.

Col. Albert A. Pope. Col. Albert A. Pope, whose death we chronicled in our last issue, was one of the most prominent figures in the automobile industry, having been president of the Pope Manufacturing Company and an active member of various trade organizations. He was born in Boston, Mass., on May 20, 1843, and was therefore in his sixty-seventh year at the time of his death. In his boyhood he worked on farms and in factories. and he was a typical self made man. The Pope Manufacturing Company was organized by him in 1877 for marketing small patented articles. In 1878 the manufacture of bicycles was begun, in which line of industry the company became very prominent. Colonel Pope took great interest in the good roads movement, and also founded a

COL. A. A. POPE.

cycling publication, The Wheelman, which is still in existence under another name.

After the collapse of the bicycle boom Colonel Pope turned his attention to automobiles. A portion of the Pope Manufacturing Company factory in Hartford was devoted to the manufacture of electric vehicles as early as 1897. In 1902 the subsidiary Pope Motor Car Company, after having built a few two cylinder and three cylinder cars, turned out a four cylinder machine which was classed among the leading makes in this country. same company produced electric vehicles in a plant in Indianapolis. The Pope Manufacturing Company, at its Hartford plant, began the manufacture of single cylinder gasoline cars, known as the Pope-Hartford, in 1904. Later a double cylinder opposed car was produced there, and finally a four cylinder, vertical, shaft driven car, which is still being turned out under the Pope name. In Hagerstown, Md., the company produced low priced single and double cylinder cars. At one time in their history the Pope companies manu-

factured automobiles of the single, double and four cylinder gasoline types, varying widely in price, and electric vehicles in considerable variety.

During the summer of 1907 the Pope Manufacturing Company, under the stress of the approaching financial panic, went into receiver's hands, one of Colonel Pope's sons being appointed co-receiver. During the receivership period several of the company's plants were disposed of, including the Waverley electric vehicle plant in Indianapolis, the Toledo, Ohio, plant and the Hagerstown, Md., plant. The receivers were enabled, with the receipts from these sales, to pay the indebtedness of the company in full, and they were discharged some time ago.

Colonel Pope had been in ill health since the failure of the bicycle industry, some ten years ago. Since July 9 last his condition was serious and his death was not unexpected.

Continental Motor Manufacturing Company Increases Capital Stock.

The Continental Motor Manufacturing Company, Muskegon, Mich., has increased its capital stock from \$250,000 to \$500,000. Of the total amount \$475,000 is common stock and \$25,000 preferred stock, earning 6 per cent, dividend and subject to redemption September 1, 1911. Of the new issue \$34,500 was subscribed for and apportioned pro rata among the old stockholders at a recent meeting, and the remainder is subject to action of the stockholders.

#### Auto Activity Booms Flint, Mich., Real Estate.

Reports from Flint, Mich., show conditions which are most unusual for any established city. It seems that the automobile business there has grown so rapidly that a great many workmen have collected from other cities. They have come in such numbers that houses have not been built fast enough to accommodate them, and many are living in tents. A probable reason for the failure to build houses is that the prices now asked for Flint real estate, both city and suburban, are so high that most builders consider them prohibitive.

#### Foreign Trade Opportunity.

There is a growing market for motor cars in a state in the Far East, according to an American consul there. He forwards a report on the subject, and appends a list of names of persons with whom American manufacturers of motor cars would do well to communicate. A copy of the report and list of names may be had by interested firms upon application to the Bureau of Manufactures. Refer to No. 375).

#### Business Trouble.

Walter H. Mitchell, doing business at the Hillman Auto Supply Manufacturing Company, 485 Tremont street, Boston, Mass., has made an assignment to Francis Hurturbis, Jr., and Chas. M. Shenton.

#### ommercial Applications.

#### A New Farm Tractor.

Gas Tractor Company, of Minneapon, which is said to have sold a cone number of motor farm tractors in Nebraska and Oklahoma, is seekcation near the centre of the source and for its product. Kansas City, naha, Neb., and Wichita, Kan., are onsidered. M. L. Lang, a repree of the company, said to a Horse-GE representative in Kansas City company intended not merely to the tractors at the new plant arts manufactured in Minneapolis, completely manufacture them there. City, he said, was looked upon y by the concern, owing to its geo-I location and fine shipping facilialso because it is already a dispoint for farm machinery on a

of the company's tractors is being by J. A. Kyle, who lives near Kan. He farmed 1,000 acres last When the Glidden tourists passed le's place the tractor was pulling disc plows behind, to which was ata heavy surface packer weighing ounds, which rolls and packs the n tightly to prevent the rapid evapof the moisture. The ground was mmediately after the harvest, and nain in that condition and take up fall until September 20, after which be seeded in in wheat. The tractor to turn and pack 30 acres a day, gallon and a half of gasoline per d I gallon of lubricating oil to acres. Two men usually work on or, though it is said that one could t. A self guiding wheel follows ow ahead of the big driving wheels, once set the tractor will go clear he field without attention, or if n a circle will continue its work

GAS TRACTION COMPANY'S FARM TRACTOR,

as long as the gasoline holds out and nothing goes wrong. The propelling power is furnished by a four cylinder, 90 horse power motor.

Milwaukee Fire Chief on Motor Fire Engines.

Chief Thomas A, Clancy of the Milwaukee (Wis.) fire department, speaking before the annual convention of the Wisconsin Paid Firemen's Association at Madison, gave marked approval to motor fire apparatus. Although he did not advise the purchase of self propelled vehicles for all purposes, he urged strongly the use of the motor car by chiefs and assistant chiefs in getting to fires. He gave interesting figures based on his experience with a touring car, a municipal car. In the two years he has had the car Chief Clancy responded to more than 600 alarms. The cost of gasoline has averaged \$10 a month; oils, \$25 a year. In twenty-two months the car consumed 1,200 gallons of gasoline. The third set of tires is now being used. He said he believed

motor apparatus is of greater advantage in smaller cities, where there is no traffic congestion, and where the distances are shorter. Mr. Clancy expressed the belief that heavy motor apparatus has not yet reached the point of perfection required. His car, however, is a great saving and highly satisfactory in every way.

#### Commercial Notes.

It is reported that W. H. Delany, of the Hotel Imperial, New York city, will import 500 Napier taxicabs.

C. H. Edwards, W. A. Day and C. S. Wilson, of Trinity, Cal., have established a motor stage line between Redding, Shasta County, and Weverville, Trinity County, with a seven passenger, 70 horse power touring car.

The West Philadelphia section of the United Gas Improvement Company has recently been equipped with five electric trucks, three for the meter inspection department and two for carrying piping. All of them are of General Vehicle Company

OVERLAND MOTOR MAIL WAGONS AT INDIANAPOLIS POST OFFICE.

(This service has been referred to in a recent issue.)

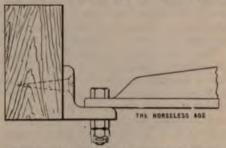

steel cross members are used. The frame has a 1½ inch drop at the rear and is inswept at the forward end to increase the steering lock. On the Model R 40 inch semi-elliptic front springs are used and 50 inch three-quarter scroll elliptic rear springs, with oil cups on all hangers and pins. All springs are of nickel steel. The wheels are 36 inches in diameter, and fitted with 4 inch Fisk bolted on tires on demountable rims. The car is stated to weigh 3,000 pounds with equipment.

The Chase Surrey.

The Chase Motor Truck Company, of Syracuse, N. Y., have recently brought out a new design of car, a surrey which can be converted into a commercial runabout for the use of tradesmen, for light delivery, etc. The car is equipped with 40 inch wheels, fitted with 134 inch Firestone flat tread solid rubber tires It has a wheel base of 96 inches and weighs 1,400 pounds complete.

The motor is a three cylinder, two cycle vertical one, cooled by the Chase system of air cooling. A sectional view through one of the cylinders is shown herewith. It will be observed that the motor is of the three port type, with pre-compression in the crank case. The crank chamber is made of two iron castings bolted together in a horizontal plane through the centre of the crank shaft. The four main bearings of the crank shaft are exceptionally long and are bronze bushed. Counterweights are fitted to all of the crank arms, and the motor is thoroughly balanced.

The cylinders are of 41/8 inches bore and stroke respectively, and the motor is rated at 18 to 20 horse power. The arrangement of the ports is the same as in a conventional three port engine, except that the transfer passage is con tained entirely within the cylinder casting, and opens into the crank chamber through ports in the cylinder wall and the piston wall. This reduces the length of the passage, and should reduce the resistance encountered by the charge in passing from the crank chamber to the cylinder. The top of the piston is slanted downward from the upper edge of the deflector plate. Light drop forged connecting rods are used, and hollow wrist pins. The cylinders are cast with annular flanges on their side walls and vertical flanges on the head. The flywheel is developed in the form of a centrifugal fan, resembling a paddle wheel in general appearance. The action of the flywheel is to draw air into the bonnet

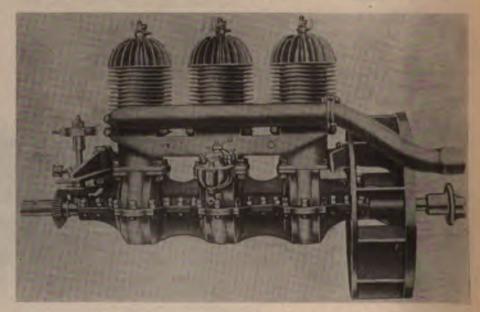

SECTIONAL SKETCH OF CHASE FRAME.
(Not to scale.)

space, which is open in front, and over the cylinders, and to force it out around its circumference. A dustpan underneath the engine, conforming to the circumference of the flywheel, renders the air circulation more effective.

A Holley carburetor is used, and connects through a cast iron manifold with the crank case inlet ports of the three cylinders. Fuel is carried in a 10 gallon tank in the front seat, and is fed to the carburetor by gravity. The Atwater Kent unisparker is employed for ignition. The make and break device is carried on a vertical shaft in front of the motor, and is driven by mitre gears from the crank shaft, and the coil is secured to the dashboard. The current for ignition is furnished by a dry cell battery. Only a single set of cells is carried, which furnish current for 500 to 700 miles. The oiling system of the engine is exceedingly simple. There are no oilers or oil cups of any kind on the engine, except one grease cup on the timer shaft, all wearing parts being lubricated by oil mixed with the gasoline before it is poured into the tank However, each of the main crank shaft bearings is provided with an oil tube for emergency lubrication by means of a squirt gun. These tubes are closed by spring pressed steel balls. It is the custom to mix I quart of oil with every 5 gallons of gasoline. This lubricating system is said to have proven particularly satisfactory in connection with delivery wagons of small tradesmen, which are often operated by apprentices. It is impossible to either adjust the lubrication improperly or to entirely forget turning the oil on. The amount of lubricant used is in exact proportion to the work done by the engine, and there is therefore no possibility of excess lubrication, with its attendant sooting of plugs and foul ex-

Directly back of the engine is located a single universal joint, from which a driving shaft extends to the encased planetary change speed gear, which is built in one unit with the bevel gear and differential on the countershaft. The change gear gives two forward speeds and one reverse, and is of the conventional type with fibre disc high speed clutch and bronze low speed and reverse brakes. The countershaft is mounted in Hyatt roller bearings. The bevel gears

CHASE THREE CYLINDER, TWO CYCLE, AIR COOLED MOTOR.

#### Los Angeles Garage Ordinance.

The Los Angeles, Cal., council has passed an ordinance regulating the conduct of garages, which is awaiting the signature of the mayor. It defines a public garage as a building where automobiles are kept or stored by the public, or are rented to or hired by the public, or where a charge is made for the use, storage or keeping of automobiles. A private garage is defined to be a building in which one or more automobiles are kept or stored for private use only.

For all new garages to be opened a permit must be obtained from the fire commission, and all garages must comply with the regulations as to gasoline storage. Applications made under the ordinance are to be referred to the fire marshal for investigation and report as to whether the establishment complies with the ordinance. It is provided that the fire commission shall revoke any permit if the ordinance is violated, but not without a public hearing.

Every building hereafter erected and every building hereafter altered for use as a public garage shall be of fireproof construction. Among other requirements is one that there shall be two chemical fire extinguishers provided for the first 500 square feet of floor space, and one for each additional 500 square feet. Four barrels of clean, dry sand, each provided with an iron scoop, are required to be kept in every public garage, to be used in extinguishing oil fires.

It is unlawful to maintain a public or private garage in any building used as a hotel, apartment house, rooming house or lodging house. It is also unlawful to keep more than 5 gallons of gasoline inside of any public or private garage, except such as is cortained in the tanks or reservoirs of automobiles stored in such garage; provided, however, that this shall not prevent the keeping of gasoline in portable filling tanks ir buggies, as provided in another portion of the ordinance. Only one portable filling tank or buggy, containing not to exceed 50 gallons of gasoline, is permitted in one garage. These tanks must be mounted on metal wheels, with rubber tires, and each one shall be equipped with a pump, fitted with a hose attachment not to exceed 8 feet in length, with a ground shut-off nozzle at the end. Gasoline must be pumped into the automobile from this tank. No tank of this construction may be used until the type or design shall have been approved by the fire commission.

Gasoline must be stored in tanks outside the walls of garages. These tanks may have a capacity of 200 gallons, except that not more than 400 gallons may be stored

for a public garage or more than 200 for a private garage.

Gasoline may only be stored in locations approved by the fire board. It is made unlawful to keep or carry about in any garage any gasoline in an open container. The portable tank must be kept at all times within 10 feet of the entrance of any garage. Smoking in any public garage is forbidden and signs to this effect are required to be displayed. Accumulation of sawdust, rags or rubbish about garages is also forbidden, unless kept in closed metal containers. Naked flames of all sorts are forbidden.

The fire marshal is authorized under the ordinance to enter any garage at any time to inspect it, and it is made unlawful to refuse him admittance or to interfere with him or any of his deputies.

The penalty for violations of the ordinance is a fine of from \$5 to \$500, or imprisonment for a term of not to exceed six months, or both fine and imprisonment. Each day the ordinance may be violated shall constitute a separate offense.

## To Prosecute Farmers Obstructing the Roads.

Motorists of Racine County, Wis., who have suffered long because public highways were obstructed or impeded by farmers who dislike the new method of travel, have determined to prosecute the offenders. The first case is that of Henry Plow, of Racine. against "John Doe," who is an unknown farmer. The charge is that the farmer unlawfully and unreasonably obstructed the road. Mr. Plow and party were returning home from Milwaukee when the farmer was approached. A second farmer came along, the two held a conference, and both headed toward Racine at a gait much slower than 4 miles an hour for more than 6 miles. When Mr. Plow signaled to be permitted to pass the wagons drove abreast.

## Standing By Law Proposed in Wisconsin.

A number of members of the Wisconsin Legislature are sounding sentiment among owners as to the passage of a bill at the next session providing for a penalty for failure to render assistance to persons hurt by motor cars. The proposed bill is to be known as the "standing by law," and is similar in effect to the Federal law requiring masters of vessels to stand by in cases of accident or collision. The suggestion is made that a clause be inserted in the bill making the failure to remain and render assistance prima facie evidence that driver was at fault for the accident and ground for action for damages.

## Milwaukee Motorists Fight Wheel Tax.

The Stern wheel tax ordinance now before the Milwaukee Common Council is being fought by business men and motorists on the ground that is is unnecessary and will be a hardship. The ordinance is not

likely to be passed. Its provisions are: Every barouche, sulky, cab, coupé, buggy, runabout, carriage or trap drawn by one horse, \$1.50; other one-horse vehicles, \$2. For two-horse vehicles, \$3.50 and \$6 respectively. For vehicles drawn by more than two horses, \$6 and \$10 respectively. Automobiles seating one or two persons, \$5; three to five passenger cars, \$7.50; six to seven passengers, \$10; more than seven passengers, \$12. Small motor delivery trucks, \$7.50; heavy trucks, \$15. Motorcycles, \$2.50.

## Beating Train Speed Not a Punishable Offense in New Jersey.

Frank G. Moore, of Philadelphia, who was reported to have boasted of beating a train on the West Jersey Division of the Pennsylvania R. R. with his automobile, was summoned by State Motor Vehicle Commissioner Smith, of New Jersey, to show cause why his license should not be cancelled. Mr. Moore, however, showed by the railroad schedule that the train made an average speed of less than 25 miles per hour, and as several witnesses also testified that the speed of the automobile had been kept within the legal limits his license was not revoked. The only charge that could be made against Moore was that he had used his car for racing. but it was ruled that the particular clause of the State law referred to racing between automobiles, and did not cover the case of racing between an automobile and a train.

Legal Notes.

The Kayton Taxicar and Garage Company, New York, have placed an order for forty additional Atlas taxicabs, of which make they already have twenty-six in service. The cabs are to be delivered by October 15.

Mayor D. S. Rose, of Milwaukee, Wis., has signed and placed in effect the council resolution prohibiting motor cars to occupy any portion of Grand avenue or Wisconsin street, from Seventh street to Jefferson street, longer than to discharge or take on passengers. The resolution is aimed at taxicab and for hire stands.

Owing to a delay in making the badges the Indianapolis drivers' registration ordinance will not be enforced until about September I. About 350 drivers have already applied for registration. It is expected that the ordinance will be tested by several drivers, who insist the city has the right to license and register only professional drivers and not men who drive their own cars.

The Georgia State automobile bill failed in the House of Representatives on August 9. The vote on the measure was 87 to 22, while to pass it would have required ninety-three votes. Immediately after the defeat of the bill it was moved that the House reconsider its action in defeating the bill, and the motion was adopted, so that the bill will probably come up again. Among the most important features of the bill is a pro-

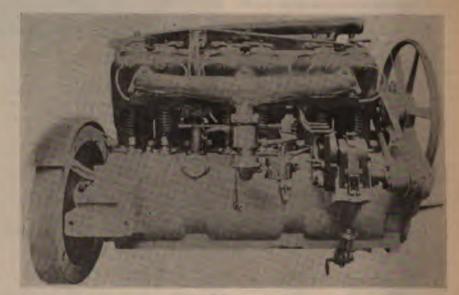

THOMAS MODEL M SIX CYLINDER, FORTY HORSE POWER TOURING CAR.

bearings being bushed with die cast babbitt bushings, which are easily renewed, since they are interchangeable. The cam shaft bearings are of bronze. The crank shaft is a carbon steel drop forging, heat treated. The connecting rods are of 3½ per cent. nickel steel. The cam shafts are also of nickel steel, as are the connecting rod bolts. The flywheel, instead of being an iron casting, as in the majority of cars, is cast of steel, and an accident due to racing of the motor is therefore impossible.

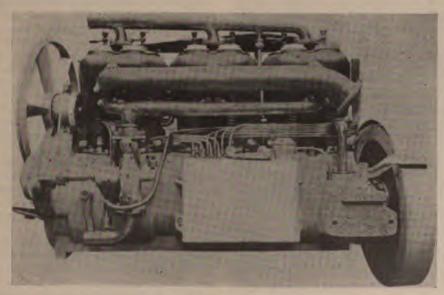

Particular effort has been made in designing the motor to insure quiet running. Thus, the cam gears are made of the herringbone type, of steel and phosphor bronze, respectively; the valve plungers have been provided with fibre inserts, and the clearance of the valve stem bearings has been reduced about 50 per cent. In order to insure absolute balance the pistons of all the cylinders are standardized in weight, all revolving parts are carefully balanced, and the compression spaces of all the cylinders are equalized.

The Thomas three disc clutch, used on former models, is retained on the Model M. The clutch disc is carried on two imported annular ball bearings, so a scarcity of lubricant will not cause dragging. Two universal joints of the internal gear type are inserted between the clutch and the change gear. It is stated that this type of universal joint has given entire satisfaction in service on motor trucks where all other forms of joints failed. The clutch is provided with cork inserts and has a double adjustment. By cranking the cross shaft of the clutch mechanism the clutch has been made much easier to operate. The change gear weighs complete only 82

The change gear weighs complete only 82 pounds, and is equipped throughout with imported annular bearings. It was designed to secure very short shafts, so as to be very rigid. The distance from centre to centre of the annular ball bearings on the countershaft is only 8% inches. Six annular bearings are used in the gear box. The gears

INLET SIDE OF MOTOR.

EXHAUST SIDE OF MOTOR

are nickel steel, case hardened, the case hardening process consisting in carbonizing in powdered bone, allowing to cool in the pot, reheating to between 1,375 and 1,425 degrees, and finally quenching in oil.

The rear axle is a Timken axle, with pressed steel casing and Timken roller bearings throughout. The bevel gears are of four pitch and give a speed reduction of 3 to 1. The company state that they tried out one of these axles on a heavy car of greater horse power without discovering any signs of weakness. The front axle, as well as the steering knuckles, are made of nickel steel. The springs are of alloy steel.

The ignition is effected by a Bosch DR-6 magneto, which furnishes current to one set of plugs, and an Atwater Kent unsparker, which supplies the second set of plugs. The engine piping is of drawn copper tubing, and is consequently quite light. Among the improved details on the new model may be mentioned the ball and

socket joints in the magneto and carburetor control mechanism, which is very closely adjustable. The wiring is carried in carefully designed housings. The fenders and running board apron absolutely protect the passengers against splashing mud.

#### Eisemann High Tension Dual Ignition System.

This system is designed to fill the demand for a magneto system which permits of starting the motor from the seat. It comprises a Type E K magneto, a non-vibrator dash coil combined with a high and low tension switch. The make and break mechanism and the high tension distributor serve for both the magneto and the coil, and the distributor is positively connected to the make and break mechanism, so that both are advanced or retarded in unison, and the distributor arm is therefore making contact with a segment at all times when the make and break contacts are in the firing position. This feature and the formation of the laminated armature core, which is of the

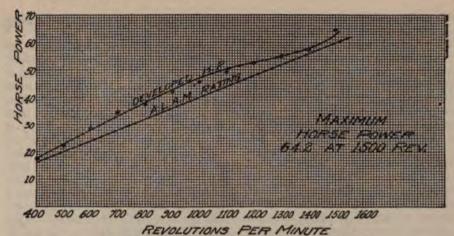

STARTING COIL.

modified H type, make the system particularly suitable for two cycle engines, because of the wide timing range of the magneto. The magnetic field is produced by two, three or four simple or double magnets, according to the size of the magneto. The pole pieces are of new design, the edges being cut along helicoidal lines instead of being straight. With this construction the armature is in touch with the pole pieces, or a greater portion of revolution than in former design, and the range of spark lag and lead will be greater on account of the more even field.

The armature is of the double T type, the central part being laminated. The primary winding is wound directly on the core of the armature, being insulated from the latter by several layers of high grade insulating silk, and the secondary winding is wound on the primary. One end of each winding is grounded, the other end from the primary is connected with the breaker, and that of the secondary with the slip ring or collector.

The starting coil includes a stationary induction coil with condenser for increas-

Horse Power Curve of Thomas Six-Forty Motor.

ing the voltage of the battery current and the switch which carries the high and the low tension currents at the same time. This switch is constructed of copper segments inserted in thick hard rubber, and is claimed to be perfectly proof against leaking and wearing.

#### The Palmer-Moore Low-High Speed Two Cycle Motor.

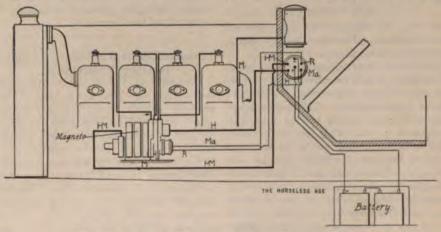

The Palmer-Moore Company, of Syracuse, N. Y., who have recently removed from 315 East Washington street to corner Tallman and Oneida streets, have had a patent allowed them on a new design of two cycle motor which they intend to develop for automobile purposes. The company have been manufacturing two cycle motors for marine work for a number of years, and the new motor is a development of their marine motor, the recent improvements enabling it to run at high speed and to develop proportionately more power.

A feature of the Palmer-Moore marine motor, and also of the new motor, is that the combustible charge is not compressed in the crank case, as in the majority of two cycle motors, but in a closed chamber underneath the piston. In the lower portion of the cylinder there is a smaller cylinder which acts as a crosshead guide. The working piston is connected to a piston rod which extends through a stuffing box in the head of the crosshead guide, and is fastened into a crosshead at its lower end.

This enables the company to get any desired amount of precompression. In the engines so far made the precompression is carried at 12 pounds per square inch. The marine motors are of the open base type, the cylinders being carried on four steel columns, as shown in the accompanying sectional sketch. The automobile motors are to be of similar construction, except that side plates will be provided for enclosing the base.

The engines are made in both a two port and a three port type. The novel feature of design above referred to consists in the provision of double transfer and exhaust ports. The two sets of ports are located one above the other, and are of the same width. The lower ports are of the same size and similarly located as those used in the slow speed marine motors, and when the engine is being operated at slow speed only these ports are effective, the upper ports being then closed by means of simple rotary valves.

The various valves are all connected together, and are held closed by means of a single spring and opened by means of a foot button. The valves consist of cold rolled steel pins of about 1 inch diameter placed in holes drilled into the cylinder castings, one side of the pins being flattened opposite the ports. The theory of the design is as follows: In order to enable a two cycle motor to run at high speed the ports must be much wider than they are

WIRING DIAGRAM OF EISEMANN DUAL IGNITION SYSTEM.

also to be slightly increased and the contour altered to permit of greater sweeps in entering and leaving the stretches.

The Kissel Motor Car Company, of Hartford, Wis., has started construction work on a new factory building 50x130 feet in size and four stories high. A new warehouse, 220x44 feet and two stories high, is nearing completion.

#### Garage Notes.

E. S. Dale will shortly open a garage in Rugby, N. Dak.

D. N. Betts, Chickasha, Okla., is rebuilding his garage, which was destroyed by fire recently.

The Aberdeen Automobile Co., Aberdeen, S. Dak., are erecting a garage at Second avenue and First street.

J. L. Hovering, San Diego, Cal., will erect a garage building at the corner of Fifth avenue and Fifteenth street at a cost of \$3,000.

R. E. Peerce, Walzenberg, Col., is having a 40x60 foot garage building erected on Main street. The building is of brick and fireproof.

C. N. Tuxbury, Marblehead, Mass., has opened his new garage on Atlantic avenue, which will be under the managership of Fred Lewis.

C. W. Bogga, McPherson, Kan., is erecting a 24x60 foot garage building on South Main street. He will do a general repair and livery business.

The Resthaven Co., of Waukesha, Wia., have purchased the lot on the corner of Hartwell and Arcadian avenues, on which they will erect a garage building.

The Missouri Motor Car Co., recently organized in St. Louis, Mo., have moved into their downtown salesroom at 1131 Olive street. H. L. Schnure is secretary of the company.

E. W. Harvey, Marysville, Cal., is taking steps to build a garage. Mr. Harvey has bought a lot at the corner of B and Seventh streets. He may also take up the manufacture of automobiles.

A four story reinforced concrete building to cost \$50,000 is to be erected in Louisa street, Oakland, Pa., in the near future for use as an automobile garage. For the site \$15,000 was paid.

The Plaza Auto Garage, 33 to 39 East Fiftyeighth street, New York city, has been leased by H. L. Crafts and H. R. Shaw, who will remodel the building and make a specialty of repair work.

The Albany Garage Co., Albany, N. Y., have purchased the property at Howard and William streets, and will erect a new building connected with their present garage. The price paid for the site is said to be \$20,000.

The Franklin Motor Car Co., Philadelphia, Pa., has let the contract for its machine shop and garage building at 3430 Chestnut street, and work is to begin immediately. The site is 39.10x120.6 feet. The new building will cost \$12,000.

A new garage is being erected on Long Beach boulevard, Long Beach, N. Y., and will be open for business at the end of this month. It is a 100x80 foot structure and has three wide entrances. A full line of supplies will be carried.

The garage which has been erected for D. B. Reigle on Marsh avenue, Kinsley, Kan., has been completed. Mr. Reigle has the agency for Regal and Oakland cars, and will do a general repair and garage business. The building is constructed of cement throughout.

The Southern Brush Auto Co. has opened show-rooms at 256 Edgewood avenue, Atlanta, Ga., to handle Brush runabouts and delivery wagons. J. J. L. Phillips, of Tifton, Ga., holds the State agency for the Brush car, but the Atlanta office will be in charge of F. H. Lincoln, of Detroit.

H. J. Lamar and F. J. Long, of Atlanta, Ga., have formed a partnership under the name of the Olds-Oakland Co., and will handle these two lines of cars at the garage now occupied by Mr. Lamar. Mr. Long was formerly connected with the Buick branch in Atlanta, but resigned to take an interest in the Olds-Oakland Co.

The Horn & Hardart Baking Co., of Philadelphia, have purchased the premises at 242 to 248 North Broad street, and will immediately erect a

three story reinforced concrete structure, a part of the ground floor of which is to be rented as an automobile garage. The premises are at present occupied by automobile firms, and they have been notified to vacate.

W. M. Gordon, Nevada, Mo., is erecting a garage building. Originally it was intended to be only a single story high, but as the owner of an adjoining hotel desired additional room, Mr. Gordon decided to make the building two stories high and rent the second story to the hotel proprietor. It is to be divided into several suites and adequately furnished, and will be connected with the hotel by an aerial passageway.

The Wichita Automobile Co., a new concern recently organized at Wichita, Kan., are erecting a \$15,000 brick garage on North Rock Island avenue. The company consists of W. O. Sterberg, Jr., and Fred Lampl. The building cwill be 50x150 feet and have a front of red pressed brick with plate glass windows. Cement floors will be laid. The building will be ready for occupancy early in September. The company expect to take on several lines of automobiles.

#### New Incorporations.

Pope-Hartford Co., Newark, N. J.—Capital stock, \$30,000.

Stevensville Rapid Transit Co., Helena, Mont.— Capital stock, \$10,000. Incorporators, R. T. Spaulding and others.

The Baker Manufacturing Co., Omaha, Neb.—Capital stock, \$10,000. Incorporators, A. S. Baker, J. S. Baker and H. T. Bailey.

Homer Motor Car Co., Los Angeles, Cal.— Capital stock, \$75,000. Directors, Lew W. Collins, A. E. Ensign and A. Schleicher.

Pitts Anti-Skid Chain Co., Chicago, Ill.—Capital stock, \$50,000. Incorporators, Jay F. Pitts, F. V. Detwiler and L. J. Schmidt.

Eureka Auto Supply Co., Chicago, Ill.—Capital stock, \$2,500. Incorporators, P. M. Henry Guerin, M. F. Gallagher and E. H. Williams.

The Electric Garage Co., Omaha, Neb.—Capital stock, \$30,000. Incorporators, George M. Redick, Denise Barkalow and Oak C. Redick.

Ferris-Dunlap Motor Car Co., Houston, Tex.— Capital stock, \$10,000. Incorporators, Floyd A. Ferris, C. E. Dunlap and Neill White.

Linkroum Automobile Co., Trenton, N. J.—Capital stock, \$20,000. Incorporators, C. Linkroum, Wm. H. Linkroum and Chas. R. Erith.

Union Motor Car Co., Newark, N. J.—Capital stock, \$125,000. Incorporators, Peter Broderson, Forcest C. Stoeers and Andrew Broderson.

C. A. Coey Auto Service Co., Chicago, Ill.— Capital stock, \$200,000. Incorporators, Chas. A. Coey, Chas. E. Gregory and D. Henderson.

Ranger Automobile Co., Chicago, Ill.—Capital stock, \$2,500. Incorporators, Frank A. Ramacciotti, Geo. A. A. Schmitt and Ernest Saunders.

Victor Windshield Manufacturing Co., Chicago, Ill.—Capital stock, \$2,000. Incorporators, John McGaffey, Arthur L. Haake and S. S. Gorham.

Essex County Overland Co., Newark, N. J.— Capital stock, \$100,000. Incorporators, Wm. F. Acker, Roland D. Crocker and Harry H. Poole.

Southern Automobile Co., Muskogee, Ind. Ter.—Capital stock, \$4,000. Incorporators, S. H. Criswell, John C. Beugler and Etta E. Criswell. Chicago Automobile Self Starting Appliance Co., Chicago, Ill.—Capital stock, \$70,000. Incorporators, C. E. Crane, Harry Hobbs and Chas.

Hot Springs Auto and Taxicab Co., Hot Springs. Ark.—Capital stock, \$25,000. Incorporators, Harry M. Westcott, E. W. Stearns and Hiram A. Whittington.

The Falls City Automobile and Garage Co., Louisville, Ky.—Capital stock, \$50,000. Incorporators, W. J. Day, R. J. Hogan, H. C. Shanks and B. B. Boles.

The Welland-Pope Co., Cincinnati.—Capital stock, \$10,000. Incorporators, H. B. McClelland, A. L. Pope, Carrie A. Pope, Clifford Welland and M. Bernhart.

Parker Motor Co., Hartford, Conn.—Capital stock, \$50,000. To manufacture motors, automobiles, automobile parts and all kinds of machinery.

Incorporators, Lucius F. Robinson, Francis W. Cole and Albion B. Wilson.

The Harper Livery and Sales Co., Charlotte, N. C.—Capital stock, \$50,000. To operate back and automobile lines. J. P. Harper, president; Dr. M. J. Ragland, secretary and treasurer.

#### Trade Personals.

R. S. Ireland, formerly Eastern sales manager of the Ajax-Grieb Rubber Co., has been made sales manager.

Chas. O. Du Mars, formerly factory salesman for the Fisk Rubber Co., has returned to Los Angeles to manage the local Fisk branch.

George S. Waite, who was formerly connected with Alvan T. Fuller, of Boston, has been appointed general manager of the Simplex Motor Car Co., Mishawaka, Ind. E. L. Thomas, son of E. R. Thomas, has been

E. L. Thomas, son of E. R. Thomas, has been appointed commercial manager of the E. R. Thomas Motor Co., Buffalo, N. Y., upon his father's return from Europe.

Sales Manager J. D. Morse, of the Citizens Auto Car Co., Hobart, Okla., has retired from the firm, which will in future be conducted by the remaining partner, W. E. Beard.

E. S. Walraven and C. M. Love have been appointed managers of the sales department of the Studebaker branch in Atlanta, Ga. G. W. Hanson continues as general manager of the branch.

K. T. McKinstry, Atlanta, Ga., has resigned his position in the automobile sales department of the Columbus Buggy Co., and has taken charge of the automobile department of E. D. Crane & Co., Atlanta, Ga.

Robt. G. Pilkington has been placed in charge of the gasoline commercial car work of the Stude-baker interests in Detroit. He is known to readers of THE HORSELESS AGE as an occasional contributor on this subject.

J. H. Raymond, for six years foreman of the repair department of the Olds Motor Works at Lansing, Mich., has accepted a position as manager of the Chippewa Falls (Wis.) Automobile Co., an agency and garage concern.

R. B. Van Dyke has been appointed manager of sales of the American Locomotive Co. automobile department, and will make his headquarters at the New York office, 1886 Broadway. Mr. Van Dyke has been connected with the Locomotive Co. for a number of years.

Frank H. Bowen, who has been actively connected with the automobile trade for the past eight years, recently with the Harry S. Houst Co. handling Thomas cars, has joined the sales force of the Simplex Automobile Co. at the new headquarters, 1860 and 1862 Broadway, New York.

#### New Agencies.

Los Angeles, Cal.-

William Mountain, Royal.

Howard Automobile Co., Chadwick.

Janesville, Wis.—Blodgett & Holmes, Ford.

Trenton, N. J.—Jonathan B. Gundling, Lozier.
Los Angeles, Cal.—Woodill Auto Co., Oakland.
San Francisco, Cal.—Leavitt & Co., Overland,
Reo, Stoddard-Dayton and Marion cars.

Atlanta, Ga.—J. E. Levi & Co., Reo and Premier.

Minneapolis, Minn.—M. R. Waters & Sons, Stevens-Duryea.

New Bedford, Mass.—Wayland L. Sturtevant, Chalmers-Detroit. Hudson.

#### Trade Literature Received.

Barrett Manufacturing Co., New York.—Road Preservation with Tarvia.

Matheson Automobile Co., Wilkesbarre, Pa.— Matheson six cylinder car instruction book.

The Oscar Lear Automobile Co., Springfield, Ohio.—Catalogue of Frayer-Miller motor trucks.

The Dayton Rubber Manufacturing Co., Dayton, Ohio.—The Dayton Airless Tire, one of Dayton's Twin Triumphs.

Thordarson Electric Manufacturing Co., 216-20 Jefferson Street, Chicago, Ill.—Catalogue of Thordarson's electrical specialties, including spectagolia.

First Automobile Journal in the English Language

VOLUME XXIV

NEW YORK, AUGUST 25, 1909

NUMBER 8

#### Simple Tests of Ignition Parts.

By W. A. STILES.

There is probably no part of the mechanism which goes to make up the modern automobile that is so little understood as is the ignition system. The average car owner understands that when his engine begins to miss fire he can change the adjustment of his platinum points; he understands that he must renew his batteries from time to time when his ampere meter shows that they are fairly well run down, but here his knowledge usually ends. Of the magneto he understands little or nothing. If he studies over the technical articles and wiring diagrams given from time to time in the trade paper to which he may be a subscriber, he sees nothing but a confusion of lines and a page or two of unintelligible technical description.

This being the case, it is small wonder that his ignition system should be the "goat" for all real and imaginary evils. Any coil or magneto manufacturer will tell you that fully 50 per cent. of the repairs sent him in the course of a year are placed on a test bench, tried out and found to be O. K. and returned to the owner. Nor are the private owners of cars the only ones who make this mistake. Repair shops, when at a loss to account for some strange behavior of the car, will often fall back on that time honored verdict, "Coil burned out." Often they are sincere in their condemnation, having persuaded themselves because the engine does not fire well that the ignition is at fault, when as a matter of fact carburetor troubles or a hundred other things may be the source of the annoyance. I have received letters from customers which read about as follows:

"GENTLEMEN-I am returning to you by express today one of your coils which is burned out. My engine started missing badly this morning, and an expert on your system whom I called in says the coil is burned out \* \* \*." (Oh, these experts!) Upon receipt of the coil a thorough examination would disclose absolutely nothing wrong, and the coil would be reshipped to the owner. The strange part of the whole affair is that the coil almost invariably "works well since you fixed it." One can easily see how much time is wasted on both sides by neglect of a thorough examination which would place the fault where it belongs. A few set rules, therefore, may not be amiss in helping the layman out of any difficulty which may seem, at first glance, to indicate ignition troubles.

TEST OF SPARK GENERATING PARTS.

We will suppose, then, that our friend, the motor car owner, has taken his family out for a Sunday afternoon spin. His engine has been running smoothly and he anticipates no trouble on the road, but after about 8 or 10 miles his machine runs jerkily and ceases to explode in the desired manner. Or it may be that the engine coughs, backfires and stops.

This is the time when he should restrain his desire to sally forth with a screwdriver and monkey wrench and prod at the "innards" of the machine. Instead he should, if his ignition system is that of a vibrator coil, first get out his ampere meter and test his batteries to see whether this may not be the source of his annoyance. While he is at it it would not be amiss to glance over them and make sure that there are no binding posts on adjacent batteries touching. Having ascertained this, the next thing is to crank the engine, if it has stopped, and endeavor to get it to run in any way to test it. If this is impossible it will be necessary to crank it by hand while the following test is being made: Remove the secondary wires, one by one, from the spark plugs, letting the engine run on three cylinders, or whatever the remaining number may be. Hold the terminal of the loose wire about three-sixteenths to onequarter of an inch from any metallic part of the mechanism, and note the spark delivered. If it is regular, without any intermittent missing, try the next one, and so on with all cylinders. Provided that they all appear to be sparking nicely, examine the spark plugs, and should these be found clean and free from split porcelains, it is a moral certainty that a good spark is being delivered to the cylinders, and that the fault lies elsewhere, probably in carburation. It may be possible that the timer has slipped, and this may easily be determined by opening the pet cocks of the engine and turning it over slowly. The spark should occur just after the air has stopped hissing out of the pet cocks on the compression stroke, which should not be confounded on four cycle engines with the expulsion stroke. Of course this is merely a rough test, but any slippage of the timer which would put the engine out of business would be easily noticeable in this way.

TEST FOR SHORT CIRCUITS.

We will suppose, however, that little or no spark is noticeable at the terminals.

The next logical thing to do is to find out whether or not the current is being delivered from the coil or magneto, and has been "lost in transit," or, in other words, short circuited. To accomplish this in the case of a coil, remove one of the secondary plug leads from the terminal post on the box, and with a short piece of wire provide an air gap of about one-quarter of an inch between this post and any primary or low tension post, which will be grounded. If, upon cranking the engine a good spark is seen, the conclusion to be drawn is that the current is being grounded somewhere between the coil and the plugs, probably by faulty secondary wiring. To test for this trouble on a magneto, remove one of the secondary leads from the distributor cap, and jump the secondary through an air gap as with the coil. The remedy for leaky secondary wires is, of course, obvious

#### REMEDIES.

Having traced the current back to the coil or magneto, we will assume that, for some reason, one or more of the high tension leads is not delivering the current. In the case of the magneto, the probability is that the fault lies in the distributor. Water or mud will sometimes short circuit one or more terminal posts, but is easily seen and as easily removed. If the trouble is that of breakage, the best advice to the average owner is to throw up his hands and have the magneto repaired at the factory or a factory branch, and not at a repair shop.

In the case of a coil, the first thing todo after having traced the trouble thus far is to try an adjustment of the platinum contacts, first loosening them a bit and then turning them up tighter. If this does not improve matters, examine all primary or low tension contacts to make sure that there is no spot of high resistance in the circuit. Examine the timer and see that the spring inside is not broken. Try all timer leads, in case there should be a broken one.

If all these things fail the coil unit is indeed burned out, and replacement is the only course.

An intermittent spark with a vibrator coil is often caused by pitted platinum points, and may be fixed by filing the latter with a very fine file, or rubbing them with emery. A uniformly weak spark at all plugs, accompanied by excessive flashing at the vibrator points, indicates a broken down condenser, the only remedy in this case also being replacement. This, is something that seldom happens, however, and trouble manifests itself slowly. A uniformly weak

spark with a magneto (high tension), especially in the case of an old one, indicates that the field magnets have become weakened, and should be remagnetized as soon as possible, although there is a possibility that the armature winding is burned out. Such things are, however, out of the hands of the novice.

If trouble suddenly develops during a rainstorm, or while riding over muddy roads, it is very probable that water or mud is short circuiting the secondary current. This is especially liable to happen on a distributor system which is not well protected from splash, and a thorough cleaning will remedy the trouble at least temporarily. Cars which are kept in public garages will often give trouble from the same cause upon starting in the morning, due to careless washing.

#### SUMMARY.

To sum up, it may be said that not once in a hundred times will trouble on a car be found due to a broken down coil or magneto. Either may be out of adjustment, or dirty, or their accessories, such as the timer, plugs, wiring, etc., be at fault. but the coil seldom. So true does this rule hold that no one should undergo the expense and delay incurred by sending a coil back to the factory without putting it to an impartial test. If it be a coil connect it up with the proper number of batteries and ground the secondary through an air gap. If it be a magneto rig it up on a bench so that it can be run at, say, 600 r. p. m., and test the secondary by grounding, as with the coil. Then, and then only, can one be sure when the coil does go back for repairs that those repairs were needed.

#### Valve Diameters.

BY F. E. WATTS.

The two most important improvements in motor design during the past two years have been a rather general increase in the length of stroke and in the valve diameter for a given bore. Both of these changes have resulted in more powerful motors with greater maximum power, and giving rather stronger torque at low speeds.

Most motors have poppet valves with conical seats, as shown in the illustration. The gas passes the scat of such a valve in a more or less perfect hollow cone, depending upon the shape of the surrounding parts of the motor. The walls of this cone will have a thickness L, depending upon the lift of the valve (see Fig. 1). The development of the opening will be that of a conical ring (see Fig. 2). The area can be found more readily, however, if the development is considered as taking the form of Fig. 3. Here the area is equal to  $2\pi R'L$ , where R' is the radius to the centre of the opening.

It is probable that for a given kind of work this area should bear an approximately constant ratio to the volume of gas which the motor cylinder handles per minute. Or

A few years ago the common inside diameters for valves were about one-third of the cylinder bore. The vertical lift of the valves varied from 1/8 inch to 3/8, 1/8, and even to 1/2 inch in some of the larger motors. The present day demands for more powerful and silent motors have altered these conditions, and at the present time the inside diameter of valves is usually from 0.4 to 0.5 of the cylinder bore. In next year's cars, so far as they have been announced, this diameter is very nearly half the cylinder bore. Most makers have settled on a vertical lift of five-sixteenth inch, which makes the dimension L about 0.22 inch for 45 degree seats.

This lift is about the maximum which can be used with ordinary valve mechanisms at high speeds without the valves becoming noisy. Some makers even use slightly smaller lifts to secure an unusually quiet

action. Since 45 degree seats are almost universally used, and all lifts are practically alike, the valve openings for different motors may be said to vary with the radius R'.

For practical motors for touring and general work the limiting piston speed may be taken as 1,000 feet per minute. For such motors valves having a clear diameter of one-half the cylinder bore are found to supply sufficient charge to maintain the torque in cylinders up to 5 inch bore. For small bore cylinders the valve diameter does not need to be so large in proportion to the bore. If we do not take into account the log of the gas or if we time the valves so as to neutralize its effects for usual speeds then the following relation should exist:

Piston displacement per minute = A constant.

or, 
$$\pi \frac{D^2}{A} P : 2\pi R' L = \pi \frac{D'^2}{A} P : 2\pi R'' L$$
,

Where D and D' are the cylinder bores. R' and R" the mean radii of the valves, and P is the piston speed (1,000 feet per minute). L is the valve lift as before.

Eliminating constants we have:

$$D^2: R' = D'^2: R''$$

Considering that, owing to the differences in the shapes of the surrounding parts, all such comparisons are only approximate, we may use for R' and R' the inside or "clear" diameters d and d'. The formula then becomes:

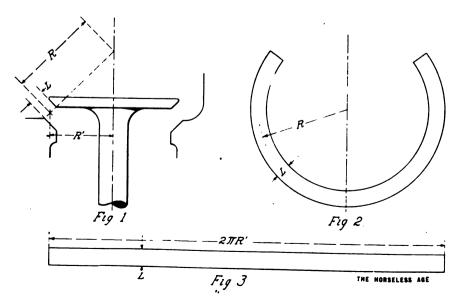

$$D^2: d = D'^2: d'$$

If for D = 5'',  $d = 2^{1/2}''$  for good supply, then for a motor with 3 inch bore d' would be found by the equation:

$$(5)^2 : 2\frac{1}{2} = (3)^2 : d'$$
  
 $d' = 0.9''$   
So  $d' = \text{only } 0.3 \text{ D'}.$ 

Nevertheless motors with bore as small as this are frequently made with valves whose clear diameter is about one-half of the bore. Such motors are consequently capal le of very high speeds and deliver a great deal of power for a given displacement per stroke. Indeed, they are so powerful and run so fast that they are likely to wear out rapidly, and quickly become noisy in the hands of the average operator. So it is probably best at the present time to sacrifice something in the way of maximum power and keep the valve diameters down to what we have suggested for a 5 inch bore, or possibly a little below that. Or if an exceptionally quiet motor is desired, the diameters may be made larger, if the bore is small enough to allow of this being done without danger of their warping, and the lift reduced a corresponding amount to give the same clear opening. These large diameter small lift valves have much to recommend them,

At the present time it is most common to make inlet and exhaust valves of the same size, and to lift them the same disstance, the greater capacity necessary for the exhaust being obtained by the longer time it remains open. This practice appears to be justified by the results obtained.

### Maintenance and Repairs

## Cost Keeping in the Repair Shop.

BY CHESTER S. RICKER.

The large repair shops in New York city are in many ways comparable to a small factory, yet methods of cost keeping applicable in the latter are often impracticable in the former. However, a system which has the earmarks of the factory has been developed and applied in one of the largest repair shops in the city. The system hereinafter described is due to Messrs. Emmerson & Lees, of New York. Their methods in six months have brought an expensive and nonpaying shop on a profitable basis, without materially increasing charges to customers. The means by which this has been accomplished may prove of value to others, and the writer will try to describe the systemas fully as space will permit.

#### COST OF WORK.

The table given by F. E. Watts in his article on "Decreasing Cost Due to Increasing

W B T O  NOTE NORMAND NAME CAR CUSTO  DATE ACT.TIME W  TARTITION  TORRIGOR TORRIGON  T	K 0-07-1

Fig. 1.

Market," in the July 28 issue of THE HORSE-LESS AGE, will be found to be applicable to the repair shop in many respects. However, to show wherein the two differ the following outline is given. A comparison with Mr. Watts' will make clear.

#### ORDERING REPAIRS.

In addition to the repair shop this company has one of the largest garages in the city, from which is drawn most of the trade which the shop has. Before any car is taken into the shop, however, the bookkeeper must O. K. the customer's account. This precaution avoids much ill feeling and trouble, as well as loss. Chauffeurs are permitted to have repairs made on their own order up to some predetermined sum, in most cases either \$25 or \$50.

#### ASSIGNMENT OF WORK,

As soon as a car arrives in the shop the necessary work required is noted by the foreman. He then proceeds to fill out the service cards, one of which is shown in blank in Fig. 1. The spaces under Car and Customer are filled in at this time, as is also the spaced designated Operation. Only one small specific operation is given on a card, and a number of cards are used for each order. Take, for example, the simple operation of relining the brakes. Cards might be made out bearing the instructions: "Take off the rear wheels"; "Remove brake shoes"; "Reface shoes"; "Replace shoes"; "Put wheels back in place." Thus five service cards might be used for a simple repair like this. All should have the same order number, however.

After the cards are filled out in this manner by the foreman they are turned over to

Cast			

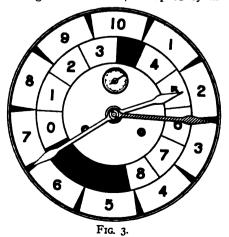

Fig. 2.

the time clerk. Unless the foreman wishes some one man to do a job, he does not give the workman's name and number. This is left to the time clerk, who can determine best to whom the job should be assigned.

In order to facilitate this allotment a special rack is provided for these service cards. This rack is within easy reach of the time clerk's desk. Each man has three places in which cards may be filed. In one are put the slips which represent the job the workman is doing at the moment. In the second are put the assignments which are to be taken up as soon as the work in hand is finished. In the third are put those which can be done at odd times when there is nothing else on hand. By this method it can be seen at a glance who will need a job next, and work can thus be allotted so as to keep everyone busy the greater part of the time. All that a man has to do under this system is to bring in his slip which covers the work just finished, and be given the next one of the series.

#### SERVICE CARDS.

Now let us take up those spaces on the card not yet considered. W designates wages, B burden, T total or shop cost, and O order number. The values given for wages, burden and total, on the top line, where these letters appear, are for the hour for this man, the burden varying according to the department in which the man is working. These values, multiplied by the

actual time, give values for wages, burden and total cost, which are entered on the card under "Cost." "Time Quit," "Time Started" and "Time Elapsed" need no explanation, except that all time is kept in hours and tenths, as will be described later.

At the end of the day, if a man cannot finish his job, he hands in the card with a check opposite "Unfinished" and an O. K. from the foreman. The next time he comes in he is given a new card with a check opposite "Continued." When the job is finally complete "Finished" is checked and the foreman O. K.'s the slip.

The space in the lower right hand corner is reserved for the bookkeeper's convenience. As each card is given to the time keeper he files it in a card index divided according to the men's numbers. Each card is filed in the order it is handed in to the clerk. At the end of the day the clerk fills in the card number, the cards being numbered consecutively from I up, beginning with the first man's and going straight through the day's cards, irrespective of the men's own numbers.

#### FILING SERVICE CARDS.

A quadruple carbon copy is made of each of these service cards. The original cards are grouped acording to their order number. The time and shop costs of this order, that is, the sum of the time and shop costs of the various operations which go to make up the order, are found and entered on a ticket similar to Fig. 2, which is then pinned to this order group.

The second copies are assorted according to the men's numbers, and sent to the auditing department to make up the payroll.

Third copies are grouped with respect to the order number and filed in the cost keeping department. In this department, also, are filed the fourth copies, but these are grouped acording to the men's numbers and also card numbers. From experience the following colored slips have been found most satisfactory: White, yellow, pink and very light blue.

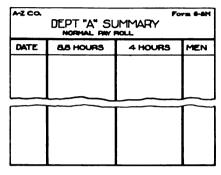

#### HOW TIME IS KEPT.

The unique dial of the time keeping clock is reproduced in Fig. 3. The hour is divided into tenths, and the normal day is 8.8 hours, but Saturdays there are only four working hours, thus making a total of forty-eight hours for the week.

During the morning hours the shaded minute hand is read, but when one returns after lunch this hand will be sixtenths of an hour ahead with respect to the hour hand and the clock divisions, because thirty-six minutes are allowed for lunch, and the clock, of course, is not stopped during that time. The hour hand will just be beginning the fourth hour when the morning minute hand has reached 12:36.

It will also be noted that the tenth divisions in reality begin three minutes late. This much leeway is purposely given each man for unavoidable delays at noon and in the morning. However,

if he comes four minutes late he loses not one or four minutes but nine.

#### DEPARTMENT SUMMARIES.

In order to lessen the work required in determining the burden charges, summaries are made up monthly for each department. Examples of the two types used are given in Figs. 4 and 5.

Department A constitutes the clerical force who receive salaries. Their time and salaries ordinarily will be entered in the non-productive column. If, however, some one in this department does productive work this is put in that column. and the difference between this and the normal salary is placed under non-productive labor. The total wages for that day will then be placed as an item on the reverse of the card. The reverse side is used only under these circumstances.

The "productive" departments also have a card, but of a different type. The one shown of Department B, Fig. 5, is the uniform type used. The items "Late per Hour" and "Cost O. T." (overtime) are the only ones which may not be self

evident. The reverse is used only when overtime work is done or when some productive man does clerical work. Each department has a different card, because the burden varies with each. The following is a list of departments into which this shop has been divided:

Depart-Department. ment. Office force. Foundry.

B. Mechanics. Electrical. C., Helpers.

D. Tinsmiths. н Road men and testers

Forge.

WORKMAN'S DAILY RECORD,

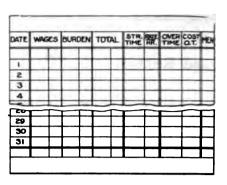

Fig. 6 illustrates the card used to keep account of each workman's daily record. A summary is made out each week in

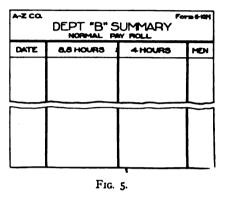

the space which is dated for Sunday. If normal time only has been worked the card is simply checked. It is from these cards that the monthly payroll record is made. The total wages are entered under that heading, and the cost of the

overtime is itemized in a separate column.

MONTHLY PAYROLL RECORD. This record, which is shown in detail in Fig. 7, scarcely needs explanation.

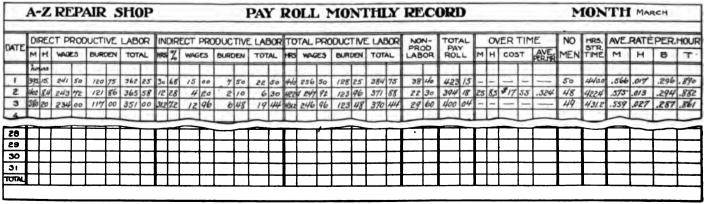

The figures and headings should make it clear. However, a few words about it may not be out of place.

The hours straight time are the sum of the hours occupied by both mechanics and helpers (M. and H.) in direct productive labor, and in addition those occupied in indirect productive labor.

The distinction between direct and indirect productive labor is that the former is work for which pay is finally received. while the latter is non-paying but necessary. The former is any repair work on a motor, for example, while the latter is exemplified in the work necessary to repair a broken lathe.

The per cent. sign indicates the proportion of hours of indirect productive labor to the total hours straight time.

This system, which has been in use only little more than half a year, replaced a very unsatisfactory system. Now that it is established it is proving not only reliable and satisfactory, but also helped to make the business profitable, while formerly it was conducted at a loss.

said to characterize the industry. Manu-

#### Car Maintenance from the Manufacturer's Standpoint.

The problems of maintenance and repair affect the automobile manufacturer no less than they do the user. Manufacturers now realize that continued success depends upon their cars making a good record in respect to low up-keep cost. Very few users know how much thought and money has been expended to give each part of their car's complex mechanism the proper size and shape to withstand the constant shocks of use and abuse, and to give to each wearing surface such an amount and texture of surface and such reliable lubrication that its deterioration shall be as low as possible, considering the permissible weight and the price at which the car is to be sold.

But, in spite of the wonderful results obtained, automobile parts do break and do wear out, and the problem of apportioning this expense in strict justice between manufacturer and purchaser is not simple. In the early days of the industry there was a more or less well founded suspicion that some manufacturers were more concerned with the quantity of their output than with its quality, and that they figured upon a larger profit from repairs than from initial sales. Such an attitude cannot now be

facturers, as a rule, are very anxious that repairs on their cars shall be low, the buying public now knowing that maintenance, repairs and depreciation, rather than first cost, constitute the real expense of automobiling. Manufacturers all recognize their responsibility for proper material and workmanship in their cars, and, while the wording of their guarantee does not include defective design, very few make more than a nominal charge for a part which soon develops a consistently bad record for wear or breakage. Results obtained from tests of materials under alternating stresses indicate that, theoretically at least, any part subject to recurrent stresses will break sooner or later, although, if a sufficient factor of safety is allowed, the life of the part may be made practically infinite. This raises the question of when the manufacturer's responsibility for the endurance of the parts of his chassis ceases. Is a part which breaks in normal service proven non-defective in material or design by the fact that it has run sixty days, six months, a year, two years? The only correct answer is the general mortality record of that part. If breakage is common the inference is that the part has not the requisite endurance, while a record of few failures would throw the blame upon abnormal strains, for which the user rather than the manufacturer is responsible. The user naturally dislikes to assume the expense of repairs, and often is honestly unable to see that the failure of some part while the car was running slowly over good roads was really the result of some overstrain which occurred perhaps months before. It is characteristic of broken parts sent back to the factory as defective that a clean, uniform break is rarely shown. Generally a darkened area shows where the initial crack started under some heavy shock, and once started complete fracture was ultimately inevitable, although it was possibly long delayed.

Where interests clash, as in this case, there is sure to be more or less friction, and while there may still be a disposition on the part of some manufacturers to evade the full measure of their responsibility, on the other hand the manufacturer must be on his guard against more or less unscrupulous attempts to saddle upon him costs which should be borne by the owner of the car. One manufacturer recently expressed the opinion that it would be a good thing for the industry if no guarantee were given, the owner paying for all repairs.

This policy would, no doubt, be satisfactory to those makers whose reputations are already established, and probably the purchaser of a car having an established record for durability would fare fully as well as under the guarantee system, but it would be very hard for a new manufacturer to establish a business.

At the other extreme are those makers who guarantee their cars against any defect developing in workmanship or material during its life. This policy can be safely adopted where a car has been built without material changes in design for a number of years, the normal life of each part pretty well established and weaknesses eliminated. In the last analysis both the life guarantee and the no guarantee plan are simply expressions of confidence in their car on the part of the makers.

Maintenance of cars on contract is obviously outside the field of the manufacturers, but when properly carried out by the local sales agent has the undoubted advantage of establishing a basis for comparison of maintenance costs in either private or public garages, and is also of value as a guarantee to the hesitating buyer that running costs (barring accidents, which may be covered by insurance) need not exceed a certain known amount. The agent's position in the matter insures the contract price being placed as low as practicable, for the sake of its influence upon sales.

The problem of the car that will go is solved. That of the future is to reduce the cost of keeping it going.

#### The Sales Situation.

Probably never in the history of the automobile industry were new companies for the manufacture of moderate priced machines being formed as rapidly as today. Although the market for these vehicles is very large, it would seem that if the present rage for promotion continues very long it will be fully supplied in a few seasons at most. But at the present time there is no dearth of people who are willing to buy, and the problem of the manufacturer is how to reach them. In the present state of the trade the only effective way to do this is apparently through local agents. Although many new agents are coming into the field, it seems that the industry has grown so enormously during the past few months that those companies who get their 1910 models on the market first will get the best both of the experienced agents and of the new comers. There is keen competition this season among agents to secure territory for the sale of a few of the better known and more popular machines, but the large increase in the number of agents for these makes it evident that the supply of experienced men will soon be exhausted.

Few who have not looked at the agency maps of some of the larger companies realize what a big market this country offers, and how imperfectly the field has been covered up to the present time. But after this season conditions are likely to be different, for if the various companies carry out the programs they have outlined they will have agents and sub-agents in nearly every place of importance.

Owing to this rapid expansion it is most important for new comers in the field to get in touch with possible agents in every way they can. While they can get plenty of people who are willing to try to sell their cars, the experienced, proven men and the likely new comers, the "live ones" in other words, are rapidly forming connections, and the later entrants to the field of manufacture, unless very familiar with the trade, are likely to get inferior men to sell their product; and find themselves fatally handicapped in the very department where a business is often made or broken.

The sales battle this season is rather to secure the proper local representatives than to reach individual buyers, and the need of the right kind of trade publicity is probably more acute than it ever was before and possibly than it will ever be again.

#### The Disappearance of the Siren.

During the past few years there have been repeated cases of automobile accessories being placed upon the market and disappearing again after a brief period of popularity, either because they served no real purpose or because they were designed to remedy some defect in construction that was eliminated in later models. One of the devices that have almost completely vanished is the siren, and we venture to say that the disappearance of no other article of equipment from the catalogues of supply houses has been the cause of so little regret among conservative motorists. Of course the siren never enjoyed any great popularity. It originally came to us from France (that is to say, as an automobile signalling device), and was adopted here by a few owners of fast cars, for whom the old fashioned "squawker" would not clear the road fast enough, or who enjoyed the sight of nervous people in horse

vehicles bobbing up from their seats when aroused by the howl of the siren.

Probably a number of causes combined led to the discarding of this offensive signal. It may have been a toy of which the owners soon grew tired, and the unpopularity achieved by the users in their own neighborhoods may have been another reason that prompted them to give it up. In some districts the use of the siren on automobiles was forbidden by law. It is also possible that the continued missionary work of automobile clubs among their members, urging them to treat other road users with due consideration, had the further effect of rendering the siren unpopular.

Not only is the tone of the siren very offensive to practically all who hear it, but the misuse of the device by arrogant youths at one time caused a great deal of bad feeling against motorists, and we may therefore be thankful that the siren is seldom heard on our highways now.

## The Economic Aspect of Auto Touring.

A great deal of money is spent each year by automobile tourists along the touring highways and in the better class of resorts, and in recent years the question of attracting auto tourist trade has been given special consideration, not only by those who cater directly to the needs of the tourists but even by municipal and State authorities. The reports in the metropolitan papers of the arrivals of auto tourists at different cities give a fair idea of the extent of the auto tourist trade, and the impression thus gained may be confirmed by personal observation at the leading hotels in the larger cities along the most popular routes, where touring parties may be seen arriving every evening during the season.

There has been some speculation recently as to the actual extent of touring, and the amount of money placed in circulation by it. It is impossible, however, to arrive at any definite figures. It is well known that on the whole auto tourists are liberal spenders. As a rule they patronize the best hotels, and in addition spend considerable money for gasoline, oil, minor repairs and garaging. We believe that the average amount spent per tourist per day en route does not fall far short of \$5. This, of course, does not cover the entire cost of touring, but only the expenses on the road. When it is considered that there are now 200,000 cars in use in this country, of

which probably more than one-half are used for either short or long tours in the course of a year, it may readily be seen that a great deal of money is scattered annually along the path by auto tourists. In the State of New Jersey between 3,500 and 4,000 non-resident licenses have been issued since the new law went into effect a few months ago. This license gives the holder the right to stay in the State eight days during a year. If we assume that on the average tourists stay in the State only four days a year, that the average number of occupants of a car is four, and that the average road expense per tourist is \$5 per day, non-resident automobile tourists carry something like \$300,-000 into New Jersey annually. It will be noted that the assumptions made are of a rather conservative nature.

Along the main highway of tourist travel, as between New York and Buffalo and between New York and Boston, the business opportunities afforded by the tourist traffic have not been neglected. These routes are placarded with the signs of hotels, garages and repair shops, and some of the garage owners have solicitors at the hotels where tourists stop, soliciting their patronage upon arrival. In the hotel lobbies also are often displayed signs and notices which afford evidence that the management caters especially to auto tourists.

The question naturally arises, What determines the itinerary of the average tourist, and how can tourists be influenced to patronize a particular section? The factors which are considered in selecting the route for a tour are quite numerous, including natural scenery, good roads, hotel accommodations, legal requirements and historical associations. Good roads are probably one of the most important factors, and a community which wishes to attract auto tourists should therefore first of all look to its roads.

#### Coming Events.

August 31 or September 30—Milwaukee (Wis.) Annual Orphans' Outing, Milwaukee A. C. September 6-11—Lowell (Mass.) Annual Motor Carnival, Lowell A. C.

September 15—Denver (Col.) Start of Flag-to-Flag Race to Mexico City, Denver M. C.

October 7—Philadelphia (Pa.) Second Annual 200 Mile Stock Chassis Race in Fairmount Park, Quaker City M. C.

November 6 to 13—National Automobile Show under the auspices of the N. A. A. M. at Atlanta,

December 29-30-Philadelphia (Pa.) Annual Midwinter Endurance Contest Quaker City M. C.

December 31 to January 7—New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

#### The Taxicab Business in Boston and Vicinity.

By H. H. Brown.

There are two large companies operating taxicabs in Boston, each operating approximately seventy-five machines. Besides these, there is one concern operating about ten machines, and another concern, which for some time past has done a regular renting business, which has fitted taximeters to one or two of its machines, and operates them under automobile rates or by meter, according to the option of the customer. Both of the larger companies have been in operation about a year.

The Armstrong Transfer Company operate eleven motor cabs at hack rates. These are mostly made with a drop seat at the side of the driver and an extension trunk rack, so that quite a large trunk can be easily carried, loaded and unloaded. This company insist that their drivers be old hack drivers of considerable experience; in fact, about all the men at present employed by this firm driving motor cabs formerly drove their horse cabs.

THE TAXI MOTOR CAB COMPANY
has its offices and garage at the Motor
Mart. The concern has been in business about a year, and operates in all about
seventy-five Thomas cabs. There are a
number of stands operated in different parts
of the city, and machines may also be ordered by telephone direct from the headquarters.

Pneumatic tires are used, of several difierent makes, but the company has no maintenance contract on them. Quick detachable rims are used, and on one or two machines demountable rims. In all other cases Stepney spare wheels are used.

The rates are 30 cents for the first half mile, 10 cents for each succeeding quarter mile, and 10 cents for each six minutes of waiting. For three or more passengers in that portion of the city below Massachusetts avenue the rates are 30 cents first third mile and 10 cents for each succeeding sixth of a mile. Also 10 cents for each six minutes of waiting. The first schedule is known as Tariff 1 and the second as Tariff 2. On the machines of this company taximeters of foreign manufacture are used, which are driven from the rear wheels.

The average daily mileage of the cabs in actual use is rather hard to obtain, but it probably varies between thirty and sixty, including both paying and no-paying miles. The drivers are paid a commission.

THE TAXI SERVICES COMPANY, with offices and principal stand at the Hotel Lenox and a garage at 12 Harcourt street, own seventy-five Berliet cabs, fifty of which are operated in Boston and the remainder in Providence, R. I. The company have been in operation a little over a year, and have from time to time increased the number of cabs in service. They expect shortly to be operating a total of 100 cabs.

This company have upward of a half dozen regular stands located at hotels and railway

stations around the city, and cabs may also be ordered by telephone at their main office. The machines are equipped with Goodyear quick detachable tires and rims. The company has a tire maintenance contract with the Goodyear company based on the mileage shown by the meters. The Goodyear company employ two men, whose entire time is given to looking after the tires. Formerly spare wheels were used on the cabs, but now each cab is provided with inner tubes, a spare tire and an air bottle.

The rates by taximeter are the regular legal rates, known as Tariffs 1 and 2. Upon the advent of the taxicab in Boston there were a number of firms who were well established in the renting business, and who were doing a good business at \$5 per hour. As the average speed of a touring car is considerably over 15 miles per hour, it will be seen that for long trips touring cars can be hired by the hour at this rate much cheaper than a cab by meter. It will be seen, moreover, that in trips of this description, that is, of one hour or more, the number of idle miles and time lost is much less than would be the case in a number of short city trips covering the same pay mileage. This company, in order to secure this class of trade, have made a rate of \$5 per hour for the first hour and \$4 for each succeeding hour, and of \$25 per day for a ten hour day and \$30 for a twelve hour day. The company also stand ready to make a special monthly rate for carriages for private use. They have this summer placed one or two cabs at some of the summer resort garages along the north shore, special rates being made with the hotel proprietors for the garaging of the machines. The taximeters are of American make, and are driven from the front wheels.

Repairs are made in the garage of the company, and on the average from twenty to twenty-five men are on the garage payroll, ten to twelve being employed in the repair shop and the rest in the garage, washing and polishing. About five machines, or about 10 per cent. of the total number, are constantly undergoing some form of repair. The manufacturers furnish all parts free for the first year. It is estimated that the depreciation, including repairs and replacements, is about 33½ per cent. per year.

When the company first started in business drivers were paid entirely on a commission basis. After an extended trial of this system it was abandoned and drivers were put on a strictly salary basis.

It was found that under the commission system the drivers, knowing they were paid by the mile, tried to cover as many miles as possible in a given time. This led to speeding, trouble with the police, and also to not a few smashups, besides excessive wear and tear on the tires and the machines. Besides this, it tended to render the service

unsatisfactory to patrons, who could not be convinced that the longest way round was the shortest way home, provided that you traveled fast enough. Hence the present salary basis. The schedule of hours now in force calls for a day of twelve hours, the first men coming on in the morning at 7, and five men coming on each hour after that till I o'clock in the afternoon. At 7 p. m. three men come on, and are on till 7 o'clock the next morning. These are old, experienced men, and are kept in reserve to answer night calls. It has been found that during the winter the busiest hours are from 2 to 6 o'clock p. m., and from 7 till 12 in the evening, the evening work being mostly theatre work. During the summer months, however, the busiest time is from 7:30 a. m. till noon, and from 7 o'clock p. m. till midnight.

The business of the taxicab companies and of the smaller concerns operating taxicabs is watched with a good deal of interest by the management of concerns operating horse driven cabs, and also by the hack drivers themselves. It would probably surprise a good many people to learn how closely the details of the business have been observed by men who are by most people thought to be all but illiterate, and what intelligent thought they have given the matter. For instance, the drivers claim that the bulk of the business of the taxicabs is from a class of customers who were at no time patrons of the horse driven cab. This, it is claimed, is largely due to the fact that the tariff is little, if any, greaterfor the full capacity of the cab than for one or two. Then, again, the minimum charges are much less than the regular legal hack rates. For instance, the lowest charge for hack fares is 50 cents for one person. The lowest charge for two persons by taximeter is 30 cents. This is for one-half a mile. As there are many residences within this distance of the Back Bay stations, many of them occupied by people in moderate circumstances, and as the car connections to the depot in this district are poor, it may easily be seen why the taxicab appeals to this class, especially when they are encumbered by hand baggage.

On the other hand, these short hauls leave a very low margin of profit as compared with the longer hauls, for the following reasons: No charge is made for sending a taxi to a call for distances of less than one mile, and there is no charge for returning from a job if the return distance is less than 2 miles. Under some circumstances the cabs must therefore cover 21/2 "non-pay" or "dead" miles to one pay mile. Under a tariff of 50 cents for the first mile the company would receive only 50 cents for an actual distance of 31/2 miles, or at the rate of 14 cents per mile. Counting 7 miles to the gallon of fuel, 3 cents per mile for tires, and driver's wages at \$15 per week, it will be seen that the amount left for wear and tear is not very large.

On the other hand, for shopping trips the hack rates are \$1.50 per hour. Take,

for instance, the case of two persons going We will say that the distance shopping. traversed is 3 miles. This would probably take by cab twenty-one minutes, leaving thirty-nine for waiting. This would cost \$1.50 for cab. By taxi the 2 miles would figure out to 90 cents, and the waiting as seven 6 minute periods, which would amount to 70 cents, bringing our total to \$1.60. Let us, however, consider that most of the time is taken up driving. With only two 6 minute stops we may expect the horse drawn vehicle to easily cover 6 miles. This would cost us by taxicab 20 cents for stops and \$2.50 for mileage, making a total of \$2.70 as against \$1.50. On the other hand, twenty-four minutes' time would be saved by the use of the taxicab, which would be a considerable advantage under certain circumstances.

#### SAUNDERS & BUTLER,

who have for a number of years run a successful renting business, fitted taximeters to a number of their machines as an experiment. This concern have no stands, their business being conducted wholly by telephone calls to their office. Their experience was that on account of the low minimum charges they lost money on these smaller trips, and that owing to the excessive cost on long trips their customers much preferred to hire by the hour or day. or in certain cases by the job, as in taking people to their destination for sums agreed upon. They found, however, that indirectly the taximeter paid them, since new customers hired their cars under taxicab rates and then became regular customers. Their machines not being built on regular taxicab lines, are not recognized as such when the taximeter is covered with a hood.

The opinion seems to be quite prevalent that the minimum charges under the taxicab tariff are too low, and that the charges for long distances are excessive.

#### WORCESTER SERVICE.

A rather interesting compromise between the taxicab tariff and hack rates is that of the Taxicab Service Company, of Worcester, Mass. This company have at present in operation six Sultan taxicabs and two touring cars. The office of the company is in the Franklin Square Garage, and their cars are garaged there under special arrangement with the proprietors. The cars are equipped with Stepney spare wheels.

Owing to the small number of cabs in operation the company have thus far not been able to obtain a tire maintenance contract.

It has been found that the average daily mileage of the machines is about 50, with the pay miles 30 to 35.

Strange to say, the gasoline consumption is as low as 1 gallon to 16 miles. Drivers are on a straight salary basis, the salary varying slightly. They are on duty as follows: Three from 7 a. m. to 7 p. m.; one from 2 p. m. to 2 a. m., and one from 7 p. m. to 7 a. m.

These machines are not fitted with taximeters but with speedometers with at-

tached odometers. The rates charged for a single passenger are as follows: One half mile, 30 cents; one mile, 40 cents; 2 miles, 80 cents. Fifty per cent. is added to the above rates for each additional passenger. Ten cents is charged for six minutes of waiting.

Calling and shopping trips are:

Two. Four.

1 mile circle of city hall, as per map. \$2.00

1 mile circle of city hall, as per map 3.00

4.00

Distances within the one mile circle may be as much as 11/2 miles, and then some time must be wasted waiting for the performance to come to an end and holding the car in readiness, so that these rates are not as high as might at first appear. Cars are furnished for business men's trips at the rate of \$3 per hour and for touring at \$4 for the first hour and \$3 for each additional hour, or \$25 per day of ten hours. This concern is practically a closed corporation, and the manager is also a stockholder and exercises very close personal supervision over the business. Drivers are forbidden to exceed 15 miles per hour under ordinary circumstances. drivers are required to serve certain time gratis in the repair shop before they are employed to drive. Thus they are made familiar with their cars, which proves helpful in case of a minor breakdown. One man is employed as repair man exclusively, and thus far no car has ever failed in service. The company started business on March 1, 1908.

## Expansion of Oakland Motor Car Company's Plant.

The Oakland Motor Car Company, of Pontiac, Mich., has acquired the property of the Pontiac Buggy Company, and will at once erect a number of additional buildings to give it a capacity of 12,000 cars a year. The plant when completed will have about 700,000 square feet of floor space and occupy 12 acres. Among the new buildings to be erected is a four story structure, 72x 140 feet, which will join the main Oakland plant and will be L shaped. There will also be a one story building built for assembling purposes, 60x200 feet. This will have a saw tooth, glass top roof. An extension will be built on the test house, to be 60x75 feet and two stories in height. Another building, 80x 160, four stories, will be built, which will be used for the assembly of the new Oakland models.

In addition to the Oakland "Forty" touring car, of which it is planned to turn out 3,000 during the next year, the company is bringing out a "Thirty" model, after designs of A. P. Brush, to sell at \$1,250. The car is equipped with a four cylinder, 4x4 inch motor, selective type change gear, multiple disc clutch, shaft drive, I beam front axle, 32x3½ inch tires, and magneto. This model will be made in both runabout and

touring car types, and will be essentially a smaller edition of the Oakland "Forty." It is planned to produce 6,000 of these cars next year, half of them runabouts and half of them touring cars.

The improvements in the "Forty" model for 1910 are of a minor nature. Among them might be mentioned a mahogany dash, which takes the place of the shroud (on the touring car); brake drums of larger diameter (14 inch); an oil tank integral with the crank case; tonneau doors with metal panels and aluminum molding; the accelerator pedal located betwen the clutch and brake pedal; a sight feed on the oil pump and a 2 gallon reserve compartment in the gasoline tank.

#### A. L. A. M. Standard Taps and Dies.

It was to be expected that after the standardization of fine screw threads for automobile work by the Mechanical Branch of the A. L. A. M., tap and die makers would take up the standard and market taps and dies to cut these threads. The American Cap and Die Company, of Greenfield, Mass., in their new catalogue list two sets of automobile screw plates for use in factories, repair shops, etc. The smaller set, known as No. 25, comprises 1½ inch dies with taps, stock and wrench, for cutting from ½-28 to ½-20 threads. The larger set, No. 35, cuts eleven sizes, from ½-28 to 1-14.

## Bowser Company Building New Factory.

F. S. Bowser & Co., Inc., of Fort Wayne, Ind., manufacturers of gasoline and oil storage apparatus, have recently been forced to make arrangements for additional factory space. In their Fort Wayne plant they had up to the first of the year 65,000 square feet of floor space, and contracts have recently been let for new buildings which will double this. The company will install 320 horse power of gasoline engines and a producer gas plant from which to supply the engines. It is stated that the company is working to its capacity.

#### Long Drive in an Electric.

A report of a long drive in an electric on a single battery charge comes from Boston. Col. E. W. Bailey, of Amesbury, Mass., recently drove one of the cars made by his company from Park square, Boston, to Providence, R. I., and back, a distance of 104 miles, and it is estimated that at the completion of the trip there was still enough energy left in the batteries to propel the car another 30 miles.

#### A Correction.

In glancing over Table I in my article on runabouts, on page 149 of the issue of August 11, 1909, I notice that the stroke of the Brush motor is given as 4 inches. This dimension was taken from a catalogue issued early this season, and the stroke has since been increased to 4½ inches.—F. E. WATTS.

# The Wider Dissemination of Professional Knowledge and Experience.

(Paper read by Henry Hess before the Society of Automobile Engineers at Chicago-Condensed.)

There is probably no professional or business man, teacher or student that has not felt the desirability, or rather the need, of preserving for future use that knowledge and recorded experience brought him by the professional journals. Much of this is later made available in books and works of reference, but those, by their very nature, must lag behind and must sacrifice much to condensation.

Out of this need have arisen many methods and systems of arranging and filing information beyond the storage ability of memory.

The inadequacy of all previous methods led a former director of the New York State Library, Melvil Dewey, to devise a new arrangement. He divided all knowledge into a series of broad classes, assigning each a number, o to 9. Each of these broad classes was again sub-divided and each such sub-division again assigned one of the numbers from o to 9.

It is apparent that this sub-division can be carried on indefinitely. For purposes of convenience a dividing period is placed after each third figure. This looks formidable in the description, but is really exceedingly simple.

One engineer will be interested in many lines, will accumulate matter along all of these, the greater part naturally relating to his specialty. He will mark each note preserved with its Dewey number. Matter in chemistry will be 540. Matter on steam engineering will be found under 621.1. In the last line he is apt to accumulate sufficient matter to make further sub-division advisable. He does that by adding figure 1; 621.11 means mechanism of the steam engine—design of engine parts. Adding 2 instead gives 621.12-marine engines and ship propulsion. As our engineer is interested also in transportation he finds that is assigned number 656; accumulating notes in quantity on this general subject further, classification by number extension gives 656.2 for transportation by railways; 656.3 for transportation by horseless vehicles, etc., while 656.32 refers to automobiles. Further sub-division goes on as far as detail sub-division may become desirable, without any change, merely by hanging on additional numbers.

All matter is filed away in numerical order. In that way our engineer wishing to consult his accumulation on chemistry need go to only one place, indicated by 540. Should he wish to refresh himself on transportation by means of automobiles, he will not have to wade through his whole accumulation on transportation under 656, but will find in its numerical order and consult only everything numbered 656.32. When through he, or anybody for him capable of reading numbers, can put everything quickly back in its numerical place. Similarly an instruction

to the office boy to pick out the complete bunch under 656.32 will bring to hand all notes on this subject. Under any other known method a fairly well trained and high order of intelligence would have to be called on to bring all of this matter to hand.

But it is necessary to know the classification number for any given subject. A so called "relative index" is used. That is an alphabetical index with the classification number given. At first sight this seems to lead back again to the alphabetical index from which escape was sought. Not so, however. There is never any difficulty in finding the broad subject under some name or other that will come to mind naturally to anyone, even superficially familiar with that subject. The index number itself then gives the clue to detail classifications, by looking up these in the "numerical extension."

Dewey started this work for his needs as a public librarian; it was extended by other librarians; a further extension to the engineering industries was made by Breckenridge and Goodenough and published by the University of Illinois. (Application to the university will bring a copy.)

One great advantage of this Dewey system is thus illustrated by the way it permits of continued extension to take in more and more detail by building onto previous work and without need for change of the previous work. At the conclusion of this paper there is presented an extension to cover the field of the automobile, this extension beginning where Breckenridge and Goodenough left off and extending their classification without break into this field and in greater detail.

Anyone interested in any specific detail in this field can carry his classification still further, building on by extension where this leaves off.

This brings me to the title of this paper, a matter that I have long advocated in a general way and that I believe would greatly benefit every engineer in every possible field; nay, more than that, would benefit every human being seeking to profit by the accumulated experience of mankind as laid down in print.

While the individual can classify his own accumulations by this Dewey method, he can benefit by the accumulation of others only when their accumulations also are indexed, not merely by the same system in general but under the same numbers. Partly this is the case today, since a number of libraries, universities and colleges have adopted the same index.

The full realization of possible ultimate benefits can be had only by co-operation. The base for such co-operation is best laid in the various professional societies. Let us take our own Society of Automobile Engineers. Say that the task of extension of the index to our direct field beyond the limits of the index appended to this paper be assigned a committee. To each member would be assigned some one subject. Say, one to extend 656.322, motive powers; another 656.323, principal parts, etc. The work is not difficult. In getting up the appended index extension, cuttings, notes, etc., as they accumulated were given the main number 656.32. As these accumulated they were from time to time assorted into more detailed groups and an extension number assigned each group. The appended extension is thus the growth of several years; the work involved was not more than a couple of hours per month. The actual work is very simple, since no logical arrangement is needed in the assignment of numbers; in fact, it is desirable to get away from any idea of logical sequence or relationship of subject as reflected in the numbers; what might appear as a very logical arrangement to one person would be not at all so to another that approached the matter from a different angle. There could. therefore, never be any wide agreement on any basis of logical sequence. Let it once be recognized that the numbers of the classification are mere location numbers and this difficulty disappears.

The committee would each six months submit its extension, and this be examined by the chairman to avoid any possible overlapping. The extension would then be recommended for general use and be made available through our publications.

The next step would be the co-operation of the various engineering societies, each taking up a special division most in accord with its field. That would avoid duplication of effort, overlapping and confusion. Each society would suggest to its members the advisability of using the index for their individual accumulations. Each would further suggest to its members that they bequeath their accumulations to the society. In this way there would gradually come to each society a great body of fully and uniformly indexed, and, therefore, immediately available, material. As it is now, such bequests are more often a source of embarrassment than anything else, since the work of reindexing is quite beyond the capacity of any society's library staff. Most of such bequests, therefore, find their way into the storerooms, there to accumulate dust. excepting, possibly, an occasional volume or two, valuable simply for its rarity. The far more useful, because live, material cannot be used. On the other hand, did that come in, properly indexed under the adopted classification, it could at once be placed on the shelves in its proper place. Naturally much of such matter would be duplicated. That would not be a detriment; on the contrary it would open up an additional and very wide field of usefulness. As it is now, the library of any of the societies, small or large, is available only to the relatively few able to actually visit it and spend time and make notes in the library's rooms during

library hours. Those most in need of the library have, therefore, the least opportunity to avail themselves of it. But with the accumulation of duplicate matter, resulting from the suggested plan, it would be desirable to keep on the permanent shelves only one copy. All of the balance would be available for lending out. Say that some member of our society, or of a society exchanging privileges with ours, wants to inform himself fully on the subject of carburetors for internal combustion motors. Writing to the society would bring in return one of the duplicate sets of everything under number 656.322.11, and at no cost to him beyond that of expressage both ways and involving no obligation beyond return by a prescribed time. Even the loss of a part of this matter would not be very serious, as its duplicate would be on the permanent shelves.

There are among the members of this society several who are interested in the editing and publishing of technical papers. These papers publish an annual index of contents. In that the headings under which articles appear are readily found, as the arrangement is alphabetical. But such headings altogether too frequently indicate anything but the important part of their subject matter. It is by no means so rare as it should be to find a good note on a carburetor, f. i., headed "Jones Latest Improvement."

No doubt at the time many were likely to associate Jones intimately with carburetors, but would it occur to them to look up such a heading in the index when searching for carburetor matter?

Now let the editor use that title if he likes it, but let him follow it with a numerical index 656.322.11. The annual index would then be marked "Carburetors 656.322.11, pp. 52, 79, 120, etc. That would guide every reader who preserved his numbers immediately to everything on carburetors in that volume. But the editor will ask why the number, why not simply the page? We do not all preserve the papers we get; some of us preserve one or two of our particular favorites. It is the habit of many to mark an article that appears to be of real interest and to cut that out for preservation. If the index reference number is printed at the head such cutting may be at once filed in proper sequence with others on the same subject. It is probable that with time the paper following this plan and bringing matter worth preserving will secure sufficient additional subscriptions to pay for the cost many times over. The actual work would not use up two hours per week of an assistant editor's time for any publication now in the field. Any editor, sure that all of his matter is worth preservation, may guard against partial loss, through filing of one article that is on the same page with another on a different subject, by either printing on one side of his paper only, suggesting the subscription to two copies instead of one, or printing advertising matter on the rear side of

each page. Both the latter suggestions will meet with the approval of the business manager; the last will supply additional arguments to the advertising solicitors for space and for the raising of the rates.

No very vivid imagination is needed to foresee the tremendous benefit that would result could the knowledge recorded in the world's professional journalism be placed freely at the disposal of all.

The plan outlined, adopted by professional societies and journals, would shorten greatly the road to the goal of "the wider dissemination of professional knowledge and experience."

AN EXTENSION OF THE DEWEY DECIMAL SYSTEM OF CLASSIFICATION TO AUTOMOBILES.

#### By HENRY HESS.

This is an extension of the classification applied to engineering industries by L. P. Breckenridge and S. A. Goodenough, as published by the University of Illinois, Bulletin, Vol. IV, November 1, 1906, No. 5, Part 1.

In the Breckenridge and Goodenough index the following numbers are assigned.

656. Transportation. Operation of Railways. Transportation, by Horseless Vehicles. Automobiles.

.321 Types.

Motive Powers. .322

.323 Principal Parts (Running Gear, Motors, Transmitting Gear, Braking Devices). Design and Construction.

Starting with these classifications, the following extensions have been made and have now been used in the classification and filing of automobile matter accumulated during the last three years. During this time the index has been gradually extended to adequately take in all matter that seemed to have any claim to preservation.

Not the least advantage of the Dewey system is the readiness with which it lends itself to this work without any serious drain on the time of a busy man. The classification so far as extended to date is given in the following pages:

```
656.32
             Automobiles.

#### To Sell Haynes Cars in Missouri.

The Haynes Automobile Company of Missouri has been organized at St. Louis to handle the Haynes car. The members of the firm are F. W. Niedermeyer, H. B. Kline and H. M. Paine. The company is to be incorporated, and will shortly open a sales office and garage on St. Louis Auto Row. A selling branch will be established at Columbia, Mo., under the management of Niedermeyer & Kline. The company holds the Haynes agency for eastern Missouri, and has placed orders for fifty cars. Temporary headquarters have been established at the Delmar Garage, 5430 Delmar avenue.

#### Automobile Motor Business Good.

Thomas J. Neacy, president of the Filer & Stowell Company, Milwaukee, Wis.. owner of the Beaver Manufacturing Company, speaking of trade conditions, said: "The Beaver works have a full year's work ahead. The output for the year ending October I will be 50 per cent. greater than for the year preceding. New equipment is being added to double the capacity for 1910, beginning with October I. The business is practically on a spot cash basis, and not, as before the panic, largely a matter of long credits."

Mitchell Motor Car Company Doubles Capital.

The Mitchell Motor Car Company, of Racine, Wis., has increased its capital stock from \$1,000,000 to \$2,000,000, an amendment having been filed with the Secretary of State last week. The additional issue is simply to keep pace with the growth of the company, it is stated at Racine.

# NEW VEHICLES AND PARTS > >

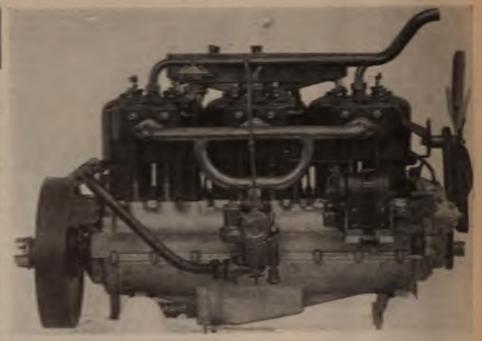

#### Pierce 1910 Models.

During the season of 1910 the Pierre-Arrow Motor Car Company, of Buffalo, N. Y., will confine themselves to the production of six cylinder machines. These will be made of three horse powers, viz., 36, 48 and 64, corresponding closely to this season's six cylinder models. Various refinements and improvements of detail have been introduced, with the result that the three models are now very similar, except in size.

THE THIRTY-SIX BORSE POWER MUREL

The cylinders are cast in pairs, with valves on opposite sides. Formerly the Pierce company used individual cylinders exclusively. The crank shaft is of large size, and, furthermore, is provided with bearings between adjacent cylinders. The bushings are of bronze, with a thin lining of special bearing metal. The connecting rods are thin I section forgings. The valves have cast iron heads, securely fastened to steel stems. The exhaust manifold is provided with two expansion joints, which are put together in such a way as to give an injector action to the outgoing gases.

Lubrication is by the well known Pierce system, giving gravity feed to all bearings from a tank located at the top of the cylinders, this tank being kept full by oil returned from the settling chamber of the crank case by a small gear pump, which is driven by worm gears from the cam shaft. A sight feed on the dash shows the level of oil in the tank. At night this sight feed is illuminated by a small incandescent bulb operated by a push button. The oil passages to the bearings are large, about one-quarter inch in diameter, and as the oil is carefully strained as it is circulated there is little possibility of their clogging. Holes drilled through the crank shaft carry the oil to the pin bearings. The cylinder walls are lubricated with the spray. An oil ring has been added to the bottom of

INLEY SIDE OF SIX CYLINDER MOTOR.

the piston in this year's models, which reduces the consumption of oil.

The hore of the 36 horse power motor has been increased one-sixteenth inch, being now 4 inches, while the stroke remains at 4% inches.

Two complete systems of ignition are used, a Boach magneto and a coil system. This year's coils, however, have six non-vibrating units, and a master vibrator which controls the adjustment for all six cylinders.

The clutch is a leather faced cone, with cork inserts. As in former Pierce models, the leather is secured with hick-ory pegs, which is claimed to prevent the burning sometimes experienced when copper rivets are used. The pedal leverage has been increased on this model, so that less pressure is required to release the clutch.

The change gear is a four speed selective. Gears and shafts are of Krupp chrome-nickel steel. The sliding pinion shaft is square. Large annular ball bearings are used. Control is by a gated lever, which operates ball locked shifting rods. It is interlocked with the clutch. The hand lever is a inches longer, and has slightly less movement than in this year's model.

The propeller shaft has two universal joints. Torque reaction is taken by a trussed rod from the rear axle. The rear axle is of the non-floating type. The shafts are of chrome-nickel, very much larger at the wheel ends than at their inner ends. In this year's cars Timken bearings are used at the wheels, while annular ball bearings are retained at the driving gears. Timken bearings are also used in the front wheels, and made necessary a new set of hub stampings. The wheels, by the way, are made from carefully selected stock, in the Pierce factory, and are said to cost two and a half times as much as those used on some cars selling at the same price. The pivots are

se.

or touring car, brougham and Front, 36x4 inch; rear, 36x41/2

than formerly. The mud guards have been changed slightly, and are provided with a flange seven-eighth inch deep all around. Spencer power air pumps are fitted to all models. They are permanently attached to the underframe, and are gear driven from the water pump shaft. The driving gear slides out of mesh, so the pump is idle except when needed. A gas tank, placed in a rear compartment, is provided for lighting. A gas generator will be fitted only on special order.

Little details are very carefully looked after on all models. Automatic grease cups are fitted on the spring joints. All working parts are bushed. This practice is even extended to brakeshoe pivots, which are bushed with bronze.

THE FORTY-EIGHT HORSE POWER MODEL.

These cars resemble the smaller machines, and have much the same improvements, most of which are common to all three models. The motor is a six cylinder, 4½x4¾ inch, similar to the others except in size. The following changes, however, apply only to this model:

The brake drums are three-sixteenth inch wider, and are made from steel stampings. The wheel base has been increased from 130 to 134½ inches by moving the front axle 4½ inches forward, bringing it under the radiator. This has given room for lowering the frame 2 inches, giving the front springs 2 inches less arch. Three-quarter elliptic springs are used at the rear, in place of the semi-elliptics used last season. The seven passenger touring body has the same

CAST ALUMINUM BODY.

seating room as this season, but has been made somewhat different in design, to harmonize with the dropped frame. Touring, landau and suburban bodies will interchange on the standard 48 and 66 horse power chassis. The chassis for the runabout and miniature tonnean bodies have a wheel base of 128 inches. These bodies will also fit the 66 horse power runabout chassis.

Tires for touring car, landau and suburban: Front, 36x4½ inch; rear, 37x5

For miniature tonneau and runabout: Front, 36x4½ inch; rear, 36x4½ inch.

In the 48 and 66 horse power models the brakeshoe joints are placed on an angle of 45 degrees with the vertical. This brings the connecting rods in such a position that the brakeshoes are not opened and closed by the motion of the vehicle springs.

THE SIXTY-SIX HORSE POWER MODEL

The 1909 model, corresponding to this, was rated at 60 horse power, and had a motor, with individually cast cylinders of 5 inch bore. The new motor is a 5½x5½ inch, six cylinder. The cylinders are cast in pairs, and other details also correspond to the smaller motors. The car embodies the following special changes:

The brake drums are t inch wider than formerly, and made from steel stampings. The wheel base has been increased to 140 inches by bringing the front axle forward 5 inches. Three-quarter elliptic springs have been adopted at the rear. The frame is dropped, and the front springs have t inch less arch, bringing the centre of gravity lower. The chassis for the runabout and miniature tonneau bodies has a wheel base of 133½ inches.

Tires for the touring ear, landau and suburban: Front, 37x5 inch; rear, 38x53/2

Front, 37x5 inch; rear, 37x5 inch.

So many precautions are taken in the manufacture of these cars to secure high quality that only a small proportion of them can be mentioned in the space available. We may note, however, the careful design of forgings, to allow the

EMPIRE "TWENTY," MODEL A.

metal to flow easily and without strain, and the exceedingly careful heat treatment of every steel part, even frames. Each piece is rigidly inspected after every machine operation. Cases are carefully hand scraped on the inside so that no grit remains to get in the oil and cut the bearings. Nearly all nuts are cotter pinned. Hoods are made of sheet copper, which probably deadens motor noises. All bodies are constructed from aluminum castings, even the closed bodies. The cast construction permits of very graceful lines. The upholstery and finish are, of course, high grade, to correspond with the workmanship of the mechanical parts.

# The Empire Twenty.

The Empire Motor Car Company, of Indianapolis, Ind., has placed on the market a 20 horse power, four cylinder model, a car that was designed by experienced men, and is the result of a long term of experimental work. Quite a number of its details are novel, although the general design does not differ widely from that of other makes which have been very successful.

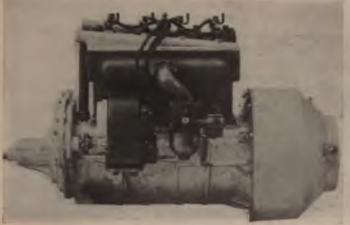

THE MOTOR.

The motor has a bore of 31/2 inches and

a 4 inch stroke. The cylinders are cast together without water passages between The valves are on opposite sides, and operated from two cam shafts. The entire interior surface of the cylinder casting is machined. Cylinder bores, valve pockets and water spaces open to this machined surface. This gives a good support for all the cores. The gas spaces are closed by an air cooled head plate, bolted to the cylinder casting with a McKim gasket between. To the top of the water spaces are bolted two water manifolds. These connect with the top of a McCord radiator. The water returns to the lower end of the jackets at the rear, through long hose connections. This gives a double thermo-siphon circula-

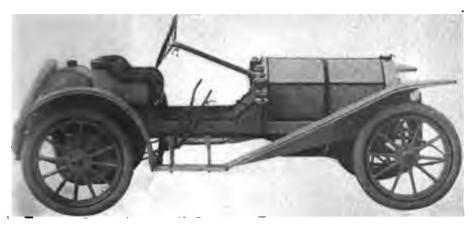

The valves are 134 inch clear diameter with a quarter inch lift; their springs are secured by screw washers, and adjustment is maintained by cap nuts, which contact with the tappets. The latter are cylindrical of large diameter, and slide in bronze guides inserted in the lower flange of the cylinder casting. Their lower ends are rounded and hardened. They are kept from turning by a cross pin.

The cam shafts are the inch in diameter, with t inch diameter bearings and integral

EMPIRE "TWENTY" MOTOR, INTAKE AND EXHAUST SIDES.

EMPIRE "TWENTY," MODEL B.

cams; they have a bearing at each end, with a distance of 12 inches between.

The crank shaft pinion is of steel and the cam shaft gears are of malleable iron. The magneto gear is die cast from a special metal. The crank shaft has two bearings. It is 11/2 inches in diameter; the pin bearings are 11/2 inches long, and the front and rear bearings are 21/2 and 31/2 inches long, respectively. The flywheel is secured to a taper. The crank shaft bushings are of Parsons bronze. The crank case is of aluminum, of the barrel type, open at the top. Large hand holes are provided. The pistons have four diagonally split eccentric rings, three above and one below the pin: the pins are clamped in the rod ends and turn in the piston. The connecting rods are neat drop forgings, 8 inches long, with caps secured by two studs. Their nuts are locked by a sheet steel strip with hexagonal holes, which fit both nuts,

Forged with each rod cap is a thin knifelike blade, between 2 and 3 inches long. These blades dip into deep oil pools in the crank case and throw a spray of oil to all the bearings. The oil pools are refilled from a tank beside the motor by a hand pump. The oiling is practically constant through a considerable change of oil level. A double system of ignition is used, consisting of a Remy magneto and batteries, with one set of plugs above the inlet valves.

# CLUTCH AND CHANGE GEAR.

The clutch is a leather faced cone. It is enclosed in an aluminum case which surrounds the flywheel. To the rear end of this case is bolted a flange which is fast on the forward end of a large diameter steel tube, the rear end of which is fastened to the change gear case in a similar manner.

The drive is by shaft to bevel gears, with a reduction ratio of 1½ to 1. From these gears two speeds and a reverse are obtained by sliding spur gears and a jaw clutch. The spur gears mesh with a pin tooth face gear. The gear is operated by a hand lever and an H quadrant in the conventional manner. The hand lever is mounted just inside the frame. This gear set is enclosed in the case which surrounds the countershaft. The ends of the case are

globular, and are mounted in the forward ends of the chain cases.

#### CHAIN CASES.

The cases are of pressed steel, and also serve as radius rods. The ball joints permit of the axle being twisted out of level without twisting the car body. Eccentric plates allow of chain adjustment, but it has been found that in a year's running there is no perceptible wear on the chains. Chain noise is entirely eliminated.

Both axles are of 2 inch diameter tubes with seven-thirty-second inch walls. The spindles are 1 fs inches in diameter. Cup and cone ball bearings are used, the inner bearings having five-eighth inch and the outer one-half inch balls. The wheels are

EMPIRE POWER PLANT.

32 inches in diameter, with 31/2 inch tires.

The rear springs are what is commonly called "full platform" or "double platform." They are made of four semi-elliptic springs, each 134x40 inches, giving a total spring length of 160 inches. The rear cross member of this spring is attached to a projection on the angle steel frame. The front is fastened to the tube which houses the propeller shaft. The front springs are three-quarter elliptics, with hinge joints, instead of the linked joints commonly used when these springs are placed at the rear. They are 1½x36½ inches.

# STEERING AND CONTROL.

Steering is by a pinion and sector gear, cross connected to the left knuckle. The spark and throttle control levers are under the wheel, on the left side. The clutch is cam operated by a pedal. This first throws out the clutch, and further movement applies the band brakes to the differential drive, which is located inside the gear case. The emergency brakes consist of bronze shoes, which expand against drums integral with the wheel sprockets. Being inside the chain cases they are fully enclosed. They are operated by the side hand lever, which is ratchet retained.

#### GENERAL DIMENSIONS AND BODIES.

The wheel base is 96 inches and the weight is given as 1,350 pounds. Two styles of bodies are fitted to this chassis. Model A has a moderately high seat, a considerably inclined 15 inch steering wheel, and a tool box mounted on the rear deck. Model B has a very much more sharply inclined 18 inch steering wheel, and a lower seat, with the gasoline tank at the rear. It is also furnished with a 1½ inch Schebler carburetor of the most expensive type, a somewhat simpler 1 inch Schebler carburetor being used on Model A.

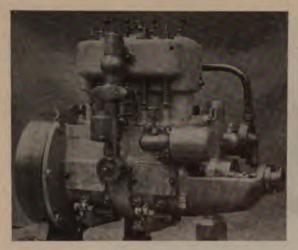

It will be seen that all working parts of these cars are very carefully enclosed. This fact, combined with the 12 inch centre clearance of both models, should make them ideal cars for use over rough and muddy roads. Model A may be geared so that its maximum speed is 35 miles per hour, giving a very powerful car of moderate speed. On the other hand the small weight and free running qualities permit of gearing Model B so as to make it a very speedy car.

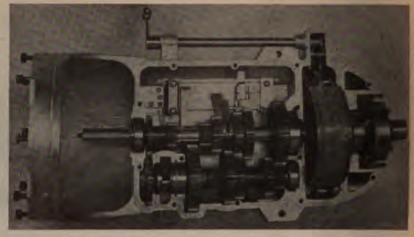

### The Saurer Two Ton Truck.

Albert T. Otto, 1876 Broadway, New York, American agent for the Saurer trucks, has just received a new 2 ton truck which contains a number of interesting features.

It is powered with a four cylinder block motor of 88 millimeters bore and 110 millimeters stroke (3½x4fs inches). The

valves are on opposite sides and interchangeable, the exhaust valves being on the left. The crank shaft is mounted on three annular ball bearings, which are of such proportions, it is claimed, that some of the engines have been run for

MOTOR AND CHANGE GEAR.

three and a half years without renewing the bearings. The engine is certainly more compact than it could be built with plain bearings of sufficient length.

The inlet, exhaust, water inlet and water outlet pipes require but a single connection each to the engine. The exhaust pipe is led straight down past the centre of the engine, and is surrounded by an air jacket from which hot air is drawn through a cored passage in the crank case to the lower end of the carburetor.

A centrifugal governor is provided, driven by a separate gear at the left of the cam shaft gear case. This governor prevents the engine from exceeding a certain predetermined speed, which may be set to suit the owner, but cannot be changed by the driver, as the adjustment is inside the case. This prevents overspeeding the engine in changing gears or in running on the low gears, and also prevents the driver from running the truck when light at a speed injurious to its mechanism.

The oil tank is located directly back of the radiator, just inside the frame, at the right hand side. The gear pump, which circulates the oil for splash lubrication, is placed inside of the tank at its rear end, and is driven from the inlet cam shaft by spiral gears and the small shaft shown in the cut of the engine just back of the governor. The water is circulated by a centrifugal pump mounted on the front of the timing gear cover and driven by a gear meshing with the exhaust cam shaft gear and a shaft, which also extends backward to drive the magneto. The water is delivered from the pump to the lower part of the exhaust valve chambers and returns to the top of the radiator through a pipe from the centre of the top of the cylinder casting. The radiator is supported from the front cross member by two bolts passing through the lower corners from front to rear, and also rests on a felt pad on the cross

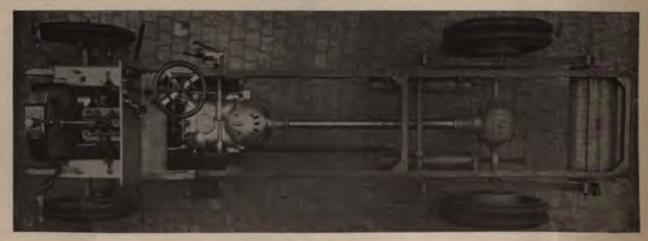

STEEL CASTING SUPPORTING FRONT OF MOTOR.

member. The fan consists of four sheet aluminum blades on a cast hub, and is supported on an L shaped round post projecting upward from the socket shown at the top of the timing gear case. A nut threaded on this post rests on the top of the socket and serves to adjust the tension of the 1½ inch leather fan belt.

Ignition is by an Eisemann low tension magneto, with single coil and high tension distributor on the magneto. No battery is used, as the self starter provided makes a battery for starting superfluous.

The engine is designed to act as a brake. The throttle lever on the steering wheel is provided with a stop as usual, to prevent closing off the supply of gas entirely. The lever can, however, be pushed past the stop. and further movement opens the inlet pipe to free air. At the same time the exhaust cam shaft is being shifted by a linkage from the throttle lever and a spiral sleeve on the end of the shaft. With the cam shaft in its normal position there is little braking effect from the engine, except that due to friction, as the air which is compressed during the up stroke of the piston is expanded again during its down stroke, returning most of the energy absorbed. However, by shifting the exhaust cams forward through an angle of about 90 degrees so that the valves open at the top of the stroke and close at the lower end, each up stroke of the piston is made a compression stroke. On one down stroke air is drawn in through the inlet valve, and on the next through the exhaust valve. At the end of each up stroke the compression is released by the inlet and exhaust valve alternately, before more air is drawn in through the same valve. The engine then absorbs power equal to about three-fourths of its nominal output at the same speed. The gears mus. of course, be shifted in going down a steep hill, and the engine is claimed to hold down

PLAN OF CHASSIS.

SAURER REAR AXLE AND PARTS.

ed of the car on any hill which it mb on the same gear. Also, by g the position of the cams only from normal, the braking power of ne is not great, and can be increased ed to the maximum available.

engine is also provided with a self device operating by compressed air. l air compressor is mounted upon inge gear case and driven by the gears seen at the extreme front end case. A special lever on the dash set in any of three positions as folhe first is the filling position. The case d to a flange on the engine crank st in front of the flywheel, thus a unit power plant, which is suptone point in front on the cast steel

front cross member of the frame and at two points in the rear upon another cross member.

The drive to the rear axle is by propeller shaft, with a single universal joint. The propeller shaft casing acts as a torsion member and distance rod. The rear axle is a full floating construction, and the casings are provided with integral flanges bolted to the bevel gear housing. Owing to the reduction in the gear case the bevel

RANDS AUTOMATIC WIND SHIELD.

gear is not large. Cam expanded emergency brakes act on the rear wheels, and the contracting shoe foot brake is entirely enclosed in the rear of the transmission year case.

The frame is of pressed steel, channel section, with truss rods to reinforce the side members. The ends of the cross member under the transmission extend below the side members and serve as truss rod

supports. Springs are all semi-elliptic. The wheels are fitted with Polack solid rubber tires, 36x5 front and 38x4 twin rear. The wheel base is 141 inches.

# The Rands No. 10 Disc Automatic Wind Shield

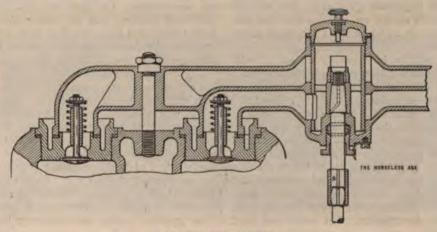

The Rands Manufacturing Company, 67-89 Fort street East, Detroit, Mich., have recently placed on the market a new design of automatic wind shield under the above name. Special claims are made as to the lightness of the shield. It will be seen from the accompanying cuts that it takes three positions, viz., vertical, inclined at 45 degrees, and folded, and it can be placed in any of these positions from the seat. In the construction of this wind shield only drawn channel tubing, Parsons manganese

DETAILS OF WIND SHIELD.

bronze castings and hard stamped brass parts are used. The glass is three-sixteenths of an inch plate glass, and is held by spring stops. The stay rods telescope.

These shields are supplied to fit any car, in three different designs. For standard touring cars the upper half is made 11 inches high and the lower half 17 inches. Where the angle of the steering column will permit of it a shield of the same height, viz., 28 inches, is supplied to hinge in the middle, bringing the division nearer to the dash. The third size is suitable for roadsters, runabouts and phaetons; it is only 26 inches in height and divided in the centre. The operation of the shield is obvious from the above cut.

SYSTEM OF STARTING.

# The Couple-Gear Gas-Electric

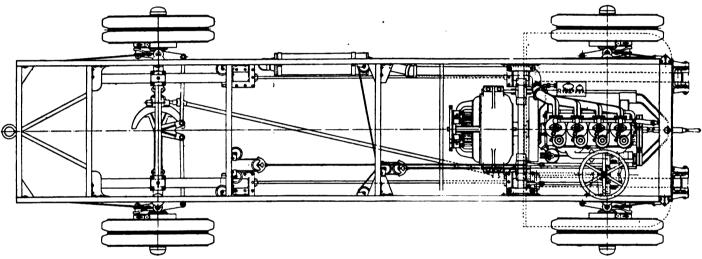

These trucks are made by the Couple-Gear Freight Wheel Company, of Grand Rapids, Mich. For the benefit of those readers who may not be familiar with it we will describe the driving mechanism, which is similar to that of the company's electric trucks. The wheels are made up from two cones of metal. Inside the case thus formed is mounted an electric motor whose frame forms part of the wheel spindle and whose shaft lies nearly in the plane of rotation of the wheel. There are two small bevel pinions, one on each end of the motor shaft. These mesh with two large bevel gears secured to the wheel, which face each other. One pinion meshes with one gear and the other pinion with the other, at a point diametrically opposite, the armature shaft being set at a slight angle to allow this. There is an equalizer I section forgings, bushed with nickel babbitt below and phosphor bronze above. The pistons have four step-jointed rings. The flywheel is 21 inches in diameter, bolted to a flange forged integral with the crank shaft. The end bearings have ring oilers, while the others are lubricated from splash pockets. Force feed is used to the cylinders and the end bearings. Ignition is by jump spark from current furnished by a gear driven magneto. A governor maintains an engine speed of 700 r. p. m., but the speed may also be regulated by throttle levers.

The generator is a six pole commutating pole type, of 12½ kilowatt capacity. This capacity is sufficient to furnish all four motors with current for a 200 per cent. overload, it is claimed. Its bearings are of plastic bronze, of the self oiling type. The generator weighs about 750 pounds and the engine about 650 pounds. Engine and gen-

storage battery, and they give the advantages of an unlimited radius of action, together with a wide range of speeds.

# Cameron Transmission for Six Cylinder Car.

The rear axle mounted three speed transmission which has been used for several years upon Cameron four cylinder cars has recently been designed to render it applicable to use upon the six cylinder, 30-36 horse power models. This transmission, as formerly built, was fully described on page 471, Vol. 21, of this journal. The above mentioned change consists in the use of two instead of three gears upon the sliding shaft, which is driven by the motor through a bevel pair and the employment of two gears instead of a single gear attached to the differential frame on the rear axle. This construction materially shortens and renders more rigid the sliding shaft, and

THREE AND ONE-HALF TON GASOLINE-ELECTRIC TRUCK.

or "evener" in the armature shaft, so each pinion does its share of the driving. With this arrangement of driving gears it is possible to get a reduction of 25 to 1.

The wires which carry current to the motor pass through the hollow wheel spindle. The spindle is mounted in a pivot, which turns in the axle fork for steering in the usual manner. All four wheels are used for driving, breaking and steering.

The combination trucks are at present made in 3½ and 5 ton sizes. We will first describe the 3½ ton machine and then note the points in which the 5 ton truck differs from it.

Power is furnished by a four cylinder motor with 5 inch bore and 5½ inch stroke. The cylinders are cast separately, with inlet valves in pockets at the side and exhaust valves overhead, both operated from a single cam shaft. The valves are of cast iron with steel stems. The tappets and cams are made from tempered tool steel.

The crank shaft is 134 inches in diameter with five bearings, bushed with die cast nickel babbitt. Bearing caps are of manganese bronze, fastened with through bolts from the cylinders. The crank case is of aluminum alloy. The connecting rods are

erator are carried on a sub-frame, which is supported at three points. The complete power plant is thus removable as a unit by disconnecting water and oil pipes, controller levers, etc.

The wheels have eleven tooth driving pinions and 33 ampere motors. The frame is of channel steel, with an over-all length of 18 feet 6 inches. The loading space is 14 feet long. The wheel base is 144 inches and the tread is 66 inches. All four springs are semi-elliptic. The tires are dual, 3½ inch solid rubber. The car weighs about 8,000 pounds and has a speed of from 5 to 12 miles per hour loaded and 10 to 18 miles per hour empty.

### THE FIVE TON TRUCK.

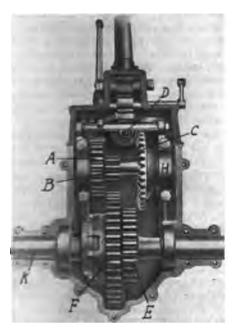

The engine of the 5 ton truck has a 6 inch stroke. The generator is a 15 kilowatt, and engine and generator weights are about 700 and 850 pounds, respectively. The gear reduction is somewhat greater, for a nine tooth pinion is used. This gives a loaded speed of 5 to 9 miles per hour and an empty speed of from 7 to 12 miles per hour. The tires are 4 inch dual solid rubber, and the weight is about 10,000 pounds. The gasoline engine and generator are found not to weigh more than a suitable

renders the gear set more compact and structurally more desirable.

The accompanying cut illustrates the new design. A is a fourteen tooth bevel pinion fast to the drive shaft and in constant mesh with the thirty-nine tooth bevel gear fast to the movable shaft H. This shaft runs at about 0.36 engine speed, and is held in large annular bearings in a frame, guided in such a manner that the shaft may be given a motion of translation to and from the vehicle axle K. Upon this shaft are slidably fixed the twenty-five tooth spur gear A and the eleven tooth gear B. To the differential housing are secured the corresponding gears E and F of thirty-one and forty-five teeth, respectively. To engage the low speed gear B is slid on shaft H into line with gear F and shaft H is moved toward the axle, these movements being effected by the motion of the gear shifting lever in selective slots. A reduction of II.4 to I is then effected.

To secure the intermediate speed gear A is slid into mesh with gear F, and the ratio engine of speed to axle speed becomes 5 to I.

The high gear is secured by shifting the sliding gears along shaft H until gear A

CAMERON TRANSMISSION FOR SIX CYLINDER CARS.

comes opposite gear E, and meshing these gears by moving shaft H toward the axle. The speed of the latter then is reduced in the ratio of 3.45 to 1.

Reverse motion is obtained by moving an idler (not shown) into simultaneous mesh with gears B and F, the ratio of speed reduction being the same as with the low gear. The gear set affords a larger difference between high and low gear than did the one formerly used. With the old transmission the ratio was 2.4, while with the new one it is 3.3.

The annular ball bearings used in this gear box are very large, and of the Cameron Company's own manufacture. In the operation of this gear set no more gears are involved when the low speed is engaged than when the high or intermediate speeds are in use, and the car is practically as quiet on one gear as on another.

# New Style of Body.

A recent European innovation in body design has been taken up in this country by the Lozier Motor Company, of Plattsburg, N. Y., who have produced what they call the Lakewood model, with a torpedo type of body. It is mounted on a runabout chassis, with an extreme inclination of the steering wheel and low seats. The dash is hooded in the same manner as the Briarcliff model: but instead of the front seats being open the sides are entirely enclosed, entrance to the driver's and mechanician's seat being gained through doors, making the sides of the body enclosed from dash to rear, only the shoulders and arms of the occupants of the car being visible from the outside.

Among the advantages of the new body special emphasis is laid on its dustlessness, resulting from the smooth sides, which end in a perfectly smooth, rounded rear seat. The rear tonneau seats are quite low, the

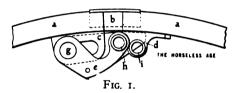

same as are the two front seats, and an unusual feature of the tonneau is an inclined toeboard, which is drawn up into position for the feet after the passengers are seated, and by means of a spring release can be dropped level when the passengers are ready to leave the car.

# The Universal Demountable Rim.

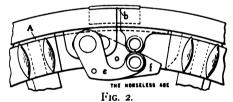

This rim, which is made by the Universal Rim Company, of Chicago, has been tried out in practical use for some time on taxicabs as well as private cars in and around Chicago, and has been found quite satisfactory, owing to its simplicity and the rapidity with which it can be placed in position and removed from the wheel, and also owing to the ease with which a tire can be placed upon the rim.

The rim is of that type in which an ordinary clincher rim is cut across at one point and held expanded at this point about five-eighth inch, and when in position is locked on the wheel by the contraction of the rim, which is effected partly by the pressure of air in the tire and partly by a locking mechanism placed at the joint of the rim to which the tire is attached.

Fig. 1 represents the joint of this rim

Rim locked open when carried as a spare. Opened, as when carried as a spare. The two ends aa of the rim are covered by a sheet metal piece b on the inside, to protect the tire at the joint. The two halves

Rim placed in position on wheel latch in unlocked position.

c and f of the locking latch are attached to a slotted lug c on either side by the pin g, the two other ends of the latch being secured by the pin H.

The rim is held in the open position

against the pressure of the air in the tire by the pin H of the locking lever which abuts against the left hand side of the lug d. The rim to which the tire is attached rests on a flat rim A on the wheel (see

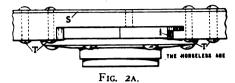

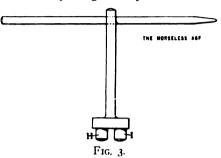

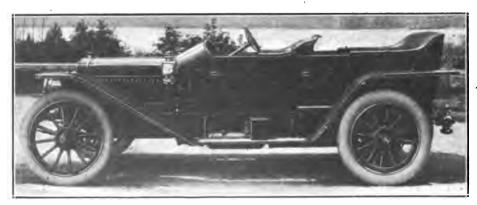

Fig. 2). A recess is cut in this rim and the felloe of the wheel, to receive the locking device, the felloe at this point being reinforced by a segmental plate S which is

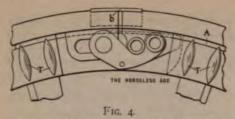

The pins H and I fit holes h and i of latch and lug d.

held in position by the T headed bolts TT (see Figs. 1 and 2). The valve stem is located opposite to the joint in the rim, and fits in a hole provided for it in the wheel. About 3 inches on either side of the valve stems are pins about one-quarter inch in diameter, which fit into corresponding holes in the wheel. Two similar pins are placed at about 120 degrees from this point. These, when the tire rim is contracted on to the wheel, effectually prevent creeping and sidewise motion.

To lock the rim on to the wheel or to unlock and remove the same, a key or tool is employed which has two pins which register with the hole H of the locking lever, and the hole i of the lug d (see Fig. 3). In either case a half turn does the business. One end of the crossbar of the tool is flattened so as to form a tire tool, which, it is claimed, is all that is necessary for the manipulation of a tire on the rim. It will be noted that the end of the plate of the latch passes into an undercut slot l of the recess into which the locking mechanism fits, this being one turther safeguard

LOZIER LAKEWOOD MODEL.

Rim on wheel with latch in locked position,

against side motion of the rim relative to the wheel. To make all doubly secure, however, a small bolt is passed through the plate S, the felloe of the wheel, the plate / and the lug d, thus securing the two ends of the rim effectively together, preventing the unlocking of the latch and insuring further against sidewise motion, the end of this bolt being provided with a wing nut. It will be seen that with the latch in the unlocked position there is no connection between the two ends of the tire rim, the plate b, which is of thin brass, simply being laid in position and held by the pressure of the air. To remove the tire from the rim the flattened end of the crossbar of the key-like tool is placed between the tire and rim, and the end of the rim is pried away from the cover; then the cover can be readily separated from the rim. The new tube being placed in the cover, the rim is replaced in a similar manner to that in which it was removed. As only a small amount of stretching of the cover is necessary, it is claimed that quick detachable tires can be used on this rim without lugs. However, those who wish to do so may use clincher tires with lugs. The makers claim that, apart from the rapidity with which the rim can be manipulated, the likelihood of the operation being interfered with by breakage or rust is practically nil, owing to the strength and simplicity of the rim, its small number of parts and the general de-

Franklin Torpedo Car.

A car with a body shaped like a torpedo has just been turned out at the works of the H. H. Franklin Manufacturing Company, Syracuse, N. Y., for the personal use of President H. H. Franklin. At what would be the water line in a torpedo the car body is of eigar shaped section, so as to minimize the air resistance. The body is long and low, and the hood is shaped like the bow of a boat. On the whole the design is a development of what is known in Europe as the "dustless body" design, the exterior being smooth, and nothing projecting below to stir up the road dust. Both the front and rear seats are provided with doors flush with the top of the dash. At the front there is only one door, however, on the left hand side, away from the driver. The car has the regular six cylinder, 42 horse power engine, but is geared higher than the stock model, and is claimed to be capable of from 60 to 75 miles per hour.

The equipment of this car is said to be exceedingly complete. It includes such items as an electric cigar lighter, special monogram stationery, caps, goggles, gloves, maps, toilet articles and a "first aid to the

injured" outfit. The name "Franklin Torpedo" is engraved on a silver plate secured
to the highly polished Circassian walnut
dashboard just above the hood. The point
of the hood is surmounted by a small silver
American eagle. A novelty among the
equipment consists of a circular wind shield.
It has a glass about 1 foot in diameter, and
is held by an adjustable nickel standard
close to the face of the driver. This wind
shield was specially designed for the Torpedo. The electrical equipment includes a
speedometer, light and small electric auxiliary lights for the oil side and rear lights.
Acetylene headlights are fitted.

The seats are low and are heavily upholstered with goat skin of a light chocolate

FRANKLIN TORPEDO.

hue. The same material is used for the rest of the interior. The exterior metal work is of polished nickel. The body is made of aluminum, and its battleship gray is striped with pearl gray; on the sides appears Mr. Franklin's monogram. The aluminum is given a rubbed instead of a highly polished finish.

The top, instead of being the regular black, is made of dark blue auto cloth. Long sloping mud guards surmount the forward wheels, harmonizing with the long, ununbroken lines of the car; semi-circular ones surmount the rear wheels. A Nightingale whistle is carried instead of a horn.

The emergency brake and gear change levers are just without the side of the car instead of inside. A circular hood of regular Franklin design is made interchangeable with the one of prow design; the latter provides for the admission of the cooling current for the air cooled engine by means of a row of openings in the top of the hood.

# The Middleditch Two Cycle Fuel Injection Motor.

The Detroit Engine Works, Detroit, Mich., are producing a line of two cycle engines fitted with the fuel injection system devised by Benjamin Middleditch, of that city, which permits of the use of either kerosene or gasoline as fuel.

These engines are of the two port type, with spring controlled poppet valve admission to the crank case, shown at P. The fuel feed system is arranged as follows: B is a fuel bowl containing the float C. A pipe D is connected at one end to the transfer passage E, and its other end enters the bowl B above the fuel level. A is the fuel pipe leading from the supply tank, which may be at a lower level than the fuel bowl X is a ball check controlling the flow of fuel from the feed pipe and opening toward the fuel bowl. Float C also carries a ball check valve opening away from the fuel bowl. I is a fuel spraying nozzle, located nearly on a level with the top of the fuel in B, and set so as to introduce fuel directly into the cylinder at the centre of the admission port. This spraying nozzle is connected by a passage (not shown) with the bowl B, and a needle valve T is inserted in this passage to regulate the rate of fuel supply.

The action of the arrangement is as follows: On the up stroke of the piston the transfer passage E and the exhaust passage N are closed and a rarefaction takes place in the crank case O. The inlet poppet P opens against its spring and pure air enters the crank case. At the same time the rarefaction is transmitted through passage D and acts upon the surface of the fuel in B. If the float level is high enough the ball valve which it controls will keep closed and no liquid will enter the fuel bowl, but if the level is slightly too low, on account of the use of fuel in previous ex-

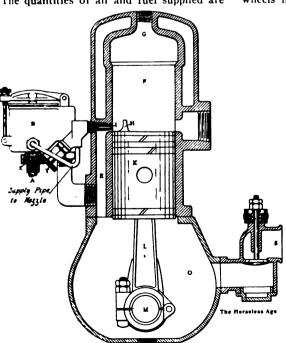

FRANKLIN TORPEDO.

plosions, the float check valve will be open and ball check X will rise from its seat under the suction, allowing fuel to be drawn into the fuel bowl to bring up the level. Compression, of course, takes place in the cylinder during this stroke, and firing, expansion and exhaust in their usual order.

On the down stroke poppet P closes and the charge of air drawn into the crank case is compressed. This crank case pressure is communicated through D to the surface of the liquid in B, and, as ball check X opens outwardly, there is no escape for the fuel, as the transfer passage E and spraying nozzle I are closed by the piston. When, however, the piston nearly reaches its lowest point the transfer port is uncovered and the compressed air in the crank case rushes into the cylinder against the baffle plate H. At the same time the spraying nozzle I is uncovered and fuel is energetically sprayed therethrough under the influence of the gaseous pressure on the surface of the liquid in the fuel bowl. The fuel and air are mixed upon entering, and their entrance tends to scavenge the cylinder, as in all engines of this type. The above enumerated actions are repeated indefinitely so long as the engine is in opera-

It will be noted that the amount of air entering the crank case depends upon the extent to which poppet P opens during the up stroke of the piston. This is regulated by the adjustable throw stop R, which is virtually a throttle. The smaller the throw which is allowed P the less the amount of air admitted will be and the lower will be the crank case pressure. The lower the crank case pressure the lower will be the pressure communicated through passage D to the surface of the liquid in the fuel bowl and the less will be the pressure resulting in forcing fuel through I into the cylinder. The quantities of air and fuel supplied are

Two Cycle Motor.

thus interrelated, and tend to maintain a constant proportion. No fuel is admitted to the crank case, and there is therefore no effect produced upon the lubricating oil there used.

By means of the valve throw stop R a wide range of speed and torque is attainable

It is claimed that these engines operate about equally well on gasoline and kerosenc. When the latter fuel is used the cylinder and air poppet are primed with gasoline in order to furnish an inflammable mixture for the first explosion.

# Veeder Form B Odometer.

The new model of the Veeder odometer, Form B, is equipped with a new style twisted tooth gear. This style has many advantages over the old type of cut gear. inasmuch as it has all the advantages of a thin narrow faced gear for cutting the mud, and also the advantage of the wide face of tooth, which gives a greater wearing surface and allows for a side or end play. This makes close endwise adjustment unnecessary. The gear is made of steel, and it is claimed that it will last indefinitely. The bearings are much heavier and improved over the 1909 model. With this new gear and these new bearings the wearing qualities of the odometer have been greatly increased.

This type is especially adapted for trucks and heavy vehicles. The Veeder Manufacturing Company are now supplying the trade with this type of instrument.

# Novel Points in Holsman 1910 Models.

The 1910 models of the Holsman Automobile Company, of Chicago, do not differ materially from the 1909 models. The wheels have been slightly reduced in size.

The 1909 models had 42 inch front and 46 inch rear wheels, whereas the 1910 models will have 40 inch front and 42 inch rear wheels. The 1910 models have greater hill climbing power on both the low and the high gears. Nickel-chrome naked friction chains have been substituted for the driving cables formerly used. The mechanism for changing from the high to the low gear has been improved, and is now more easily operated. There has also been an improvement in manufacturing methods, especially as regards heat treatment of some of the material used. The company during the coming season will market the four cylinder model, of which a description appeared in our columns some months ago, in addition to its two cylinder cars. Its line includes runabouts, surreys and open and closed commercial vehicles.

### The Gabriel Bugle Horn.

A new product of the Gabriel Horn Manufacturing Company, of Cleveland, Ohio, is the Gabriel bugle horn, a four tube horn suitable for playing bugle calls, etc., as well as for regular signal purposes. It is operated by the exhaust from four and six cylinder motors. The horn is operated by a keyboard comprising four keys, each controlling one of the notes; this makes it pos-

GABRIEL BUGLE HORN.

sible to operate each note separately, and all sorts of bugle and trumpet calls can be correctly produced. The tone is said to be very clear and far reaching. The keyboard is fitted with a small lever for sounding all four notes at the same time for signal purposes, by simply pressing the pedal. The horn is constructed of solid brass tubing, highly polished. All joints are silver brazed, and the valves are carefully fitted.

The valves which lead to the keyboard are adjustably attached to the valves, consequently the pull can be in any desired direction, and the horn and keyboard may be located to suit the operator. A convenient arrangement of the horn is shown by the cut.

# New Witherbee Magneto.

The Witherbee Igniter Company, of Springfield, Mass., have designed a new high tension magneto. Two and four cylinder models have been made and are being tested out by their engineer and by the Maxwell and other automobile companies. We expect to publish a description as soon as they have fully settled the design.

### Test Run of 1910 Rambler.

The 1910 model Rambler touring car sent out from the factory at Kenosha, Wis., for a test run on June 22 arrived back at Kenosha on August 16 after having covered more than 3,900 miles in twenty-four days. Agents of Thomas B. Jeffery & Co. piloted the car from city to city, starting at Kenosha, and proceeding from there to Indianapolis. Louisville, St. Louis, Kansas City, Lincoln and Omaha. C. Steward, agent at Omaha, drove the car from that city to Kenosha without relief. After being overhauled the car will be sent to Kansas City to compete in the Kansas City Star endurance run.

### Location of Brakes.

Editor Horseless Age:

We have seen several articles in various papers lately in answer to inquiries of readers as to the proper location of motor car brakes. So far as memory serves us for the moment, nearly all of these replies have side stepped any definite stand, and have straddled the fence in such a way that it still leaves considerable doubt as to whether, in their opinion, both brakes should be on the rear wheel drum or one brake upon these drums, with a service brake upon the drive shaft.

We are ourselves advocates of that system wherein the emergency brake is located upon rear wheel drums of large size, operated by a hand lever, and of such surface and leverage as to instantly lock the wheels if desired by the operator. The service or running brake, we believe, should be placed upon the drive shaft, should be operated by the foot, and should be of such size and construction as to enable the operator to apply it gradually and easily.

This arrangement is strictly in accordance with all foreign practice, and has, so far as we have been able to observe, every argument in its favor.

We should like very much to hear through your columns some of the views of those who advocate the use of two sets of brakes upon the rear wheel drums.

CHALMERS-DETROIT MOTOR COMPANY.

### Dry Cell Tests.

Editor Horseless Age:

On March 30, 1909, I began a test of two standard makes of dry cells. The test was made in a two cylinder machine. Twenty cells were used, ten of each kind, and well connected as per diagram.

At the beginning of the test on

LC	, ,,	O.	
March 30	1	Total amperes,	189
	2	••	201
May 31, mileage 202	1	••	238
	:	••	208
July 9. mileage 523	1	••	207
	2	••	95
August 8, mileage 408	1	••	189
	2	Discarded.	
Record of amperes of ind	ivid	aal cells on M	arci

Lot No. 1: 18-20-19-19-18-18-19-20-19-19. Lot No. 2: 19-19-22-18-20-19-22-20-22-20.

Lot No. 2: 19-19-22-18-20-19-22-20-22-20.

Record of amperes of individual cells on July 6—

Lot No. 1: 20-20-20-20-20-23-22-20-21.

Lot No. 2: 10-10-10-12-5-10-5-7-8-12.

The same ammeter was used in this test, and is probably a good average one,

Why did both lots of cells show more amperes after two months' service than at the beginning? Does the change of temperature raise the amperage, and about what would it be under ordinary circumstances? Would it be sufficient to account for the increase shown on May 31?

Is it possible that Lot No. 1 could draw and build up from Lot No. 2? Is it possible that, connected in this way, Lot No. 2 could have furnished all the current on account of the difference of the internal resistance in each lot?

M. B. JOHNSON.

[The increase in the short circuiting current of the dry cells after two months' use is probably largely due to the higher temperature prevailing at the end of that period. According to some tests made for The Horseless Age about two years ago the voltage and current of a dry cell are increased between 20 and 25 per cent. when the temperature is raised from 3° Fahr. to 72° Fahr. In your case the aggregate amperage of one set was raised 26 per cent. and of the other set 3½ per cent. But the fact that the amperage did not increase the same in both sets shows that other factors besides the temperature entered.

If the voltage of Lot No. 2 was much higher than that of Lot No. 1 the latter would draw current from the former and build up on it. This would be the effect if there were more cells in one series than in the other. Several rows of cells should be connected in parallel only, provided their

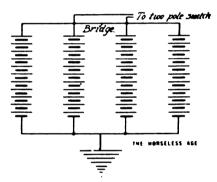

DIAGRAM OF CONNECTIONS.

voltages are alike. Whether the internal resistances are alike or not does not matter so much. With equal voltages the different rows would deliver currents inversely proportional to their respective internal resistances, but there could be no crossflow.

-ED.]

# The Interference of Wide Front Fenders With Accurate Steering. Editor Horseless Age:

The very wide, flaring front fenders, joined closely on the inside to the vehicle body, which are now in general use, and which serve their purpose so admirably, are not, however, without a slight disadvantage, which I have never seen adverted to in these columns. I refer to the fact that they absolutely cut off the view of the front view of the front wheels from the operator, and prevent him from knewing in what direction they are pointed. The steering wheel, made as it usually is, with a perfectly plain rim, gives no indication as to the inclination of the front wheels.

In ordinary driving this condition is not at all objectionable, for there is plenty of room available, and even though the car starts in an unexpected direction, when power is applied after a stop has been made, there is plenty of opportunity afforded safely to correct the direction of motion.

On the other hand, when it becomes necessary to manœuvre a car in very close quarters, as in driving out of a crowded garage or from one of the tangles of vehicles frequently encountered under congested traffic conditions, it is very desirable and highly conducive to safety that the operator should know, at all times, just how his steering wheels are pointed. There is little room for false starts, and slight accidents sometimes result from a lack of knowledge as to front wheel inclination, and consequently as to the direction in which the car will start upon the application of power. Considerable time is frequently lost in manœuvring from false movements resulting from ignorance of steering direction.

When a car is to be "cut over" from one direction of turning to the other there is no indication given the driver when the straight ahead position is passed, and it is rather difficult to estimate, without trial, how sharply the car has been "cut" in the new direction. It is not uncommon to witness a good deal of unnecessary backing and filling arising from this cause.

There would be an advantage gained, it would seem, were some indicator of steering wheel position provided, which should show the driver in his seat just how the wheels are inclined, and the writer believes that manufacturers would do well to give thought to this detail among the other small points which they are industriously working out.

The mere provision of a mark molded into the steering wheel rim, so that it could be felt as well as seen, and so placed as to be directly away from and in front of the driver, when the wheels are pointed straight ahead, would be of some advantage, although it would be useless to indicate the more acute angles of the front wheels, which are effected by more than one-half turn of the hand wheel from its straight ahead position.

Some expedient more effective than this can undoubtedly be worked out without involving undue complication. L C

# A Case of Overheating.

Editor Horseless Age:

Being a subscriber to your paper and being in trouble with my engine, I write to you for information.

I have a —— friction drive car, with a two cylinder opposed —— engine of 18 horse power. I had trouble all last summer with it heating. After running the car, say, 2 miles, the water would boil out of the radiator as soon as I stopped. I was feeding the engine even more oil than is usually required, in the hope of preventing the water boiling. I drove with the spark as far advanced as it would go without knocking. Not being able to discover the difficulty. I sent the engine back to the factory

where it was made. After doing so I received a letter from the manufacturers in which they stated: "The only thing we found wrong with the motor was that the piston rings had too much play and the gasoline escaped back through them, and this is what caused it to heat. We put in new rings, and when it was tested out it ran as smooth as any engine sent out of our factory."

This is a new engine, and the compression was very strong last summer. For this reason the repair man here could not understand how the piston rings could have been found so loose. We put the engine back in my car, and it heats just as it did last year. Thinking that perhaps the carburetor was at fault I put on a it made no difference. The radiator holds one pail of water. I understand some cars carry more water than this, two pails full. Do you think that adding an extra tank, so as to double the amount of water used, would do any good? Or can you suggest anything to overcome this heating of the engine? Any suggestion you can make will be greatly appreciated. C. A. Kortsch.

[The fact that the motor heated just the same after it was returned from the manufacturers shows that the cause assigned for the heating by the manufacturers was not the true one. In case a motor overheats it is a pretty safe conclusion that the cooling system is not doing its duty. That is, either the water is not circulating rapidly enough through the system, or the radiator is not of sufficient capacity to dissipate the heat absorbed by the jackets. We do not know what method of circulating the cooling water is used on your car, but we are strongly of the opinion that if you increase the cooling capacity you can do away with the trouble from overheating. If your water is circulated on the thermo-siphon system it would perhaps be better to install a pump, so as to insure positive circulation. The provision of a fan back of the radiator if possible, and if there is none already, would considerably add to the cooling capacity. But if you already have a pump and a fan the only remedy for the trouble would seem to be to use a larger radiator.-Ep.]

# Six Cylinder Specifications. Editor Horseless Age:

Would it be possible to make a substantial good grade automobile, weighing 1,600 pounds, of the following specifications: 112 inch wheel base, 36 inch wheels, six cylinder, 30 horse power motor, selective transmission, standard tread, clearance 11 inches, cylinders water cooled and cast in pairs, two passenger body? Would this not be an economical and speedy roadster?

J. E. M.

[A car to meet your specifications can be built, but would, we believe, be very expensive to manufacture, as all possible methods of "weight paring" would have to be resorted to. The average six cylinder, 30 horse power car, of about 112 inch wheel

base, weighs considerably more than 1,600 pounds. It would certainly be a speedy car, and, if well built, also economical to operate.—ED.]

#### Farm Tractors.

Editor Horseless Age:

Kindly give me the addresses of the firms in New York who manufacture farm tractors.

INQUIRER.

[No such tractors are manufactured in New York.—ED.]

# Motor Trucks in the Recent Massachusetts Manœuvres.

Two Packard gasoline trucks were used in the manœuvres which were held in Massachusetts during the week beginning August 15. One of the trucks was used by each of the opposing armies. The War Department at Washington, D. C., possesses very accurate figures concerning the mobility of an army under the old system. For instance, an army on foot, when in good physical condition, can cover 15 miles per day, averaging two and one-half miles per hour on the march. A division train is 15 miles long and consists of 192 commissary wagons. Each wagon to move properly and without stalling requires 60 feet of road space, and when having a four mule team hitched to it can carry 2,500 pounds. Allowance must be made for 48 pounds of oats and hay for each team per day. The following figures tend to show the superiority of the gasoline truck for this class of work:

The Packard three ton 24 horse power truck, which was used last week, covers 12 miles an hour at a governed speed, and carries a normal load of 6,000 pounds. It takes up only twenty feet of road space, one-third that required for the teams. In other words, such a truck carries more than two four-horse or four-mule teams and travels five times as fast for an unlimited distance. There is also an economy of 100 feet in road space, which means much in dispatching an army strung out in a long line over narrow roads. When an army is on a forced march through the enemy's country, scouts, pickets and outpost men try harder to kill off the horses of the invaders than the men themselves. Only a small portion of a motor truck is really sensitive to gun fire, and that can be fairly effectively protected by armor.

Perhaps the greatest advantage of a motor truck to an army in the field is the increased area of operation which it makes possible. According to old military standards, an army cannot be permanently located at more than 30 miles from its base, this being the maximum distance over which supplies can be successfully carried by horses. If a division is sent as much as 45 miles from its base it will run out of food in eleven days. With motor trucks, on the other hand, an army could be supplied at a distance of 150 miles from its base, and trucks could even be success-

fully handled at a distance of 250 miles if occasion seriously demanded it.

The Packard truck in the service of the Quartermaster's Department of the Red Army in the recent Massachusetts manœuvres, driven by Fred Robinson, on Tuesday, August 17, the rainiest day of the campaign, carried 6,000 pounds of beef a distance of more than 71 miles from the headquarters at Fair Haven to a point far to the north of Middleboro. The trip was made during the night, and such deep ruts were encountered that pebbles and rocks continually caught between the chains and rear sprockets, yet both of the chains remained undamaged. The deep mud at times stalled the car, but it extricated itself always without external assistance. The car also hauled heavy loads of baled hay. The truck was also used as a sort of hospital wagon. Hundreds of the troops on the march toward Boston were disabled with swollen feet and knees. and many of these were carried on the truck. In six days the truck covered 422 miles, generally heavily loaded, and under very unfavorable road conditions.

The Packard truck in the Blue Army carried a one pound Hotchkiss rapid fire gun. It is claimed that such a gun when mounted on a motor truck is much more dependable than when drawn by horses.

### Business Opportunities.

The cities of Beloit and Janesville, Wis., are planning to purchase motor fire engines, following the example set by the Rockford (Ill.) Common Council. The chiefs of these cities, which are close together, believe that with each department so equipped co-operation could be established.

The Milwaukee (Wis.) Common Council is considering a resolution appropriating \$4,500 for a new touring car for the chief of the fire department and \$1,000 for a runabout for the commissioner of public health. Objection has been made to the discrepancy between the appropriations, and it is likely that the sum designated for the health department will be increased.

We have an inquiry from a reader living in North Dakota as to who makes a four cylinder, shaft driven car, with 36 inch and 38 inch wheels, with solid tires, about 15 inch clearance, and either one or two seats; made somewhat like the Chase runabout, only with shaft drive. We do not know of any such cars on the market, but if any of our readers is in position to furnish it we shall be glad to forward his address to the inquirer.

The Milwaukee Board of Fire Underwriters, according to Frank J. Meyer, president, will purchase a motor insurance patrol truck before January I. The board has only three insurance patrol stations, and it is believed that with a motor truck the territory now practically unprotected can be covered without building a new station. C. F. Hibbard, chairman of the patrol committee, is in Europe, and on his return in another month the matter will be pushed.

# Commercial Applications.

# Motor Bus Lines at Asbury Park.

Two different companies are running motor bus lines this summer from Asbury Park to nearby points of scenic beauty.

Roads in this section of New Jersey are generally good, and some of the finest suburban residences in the country line the highway for miles along the shore and inland in many directions.

Rogers Red Line has two Rapid twelve passenger and one Mack twenty passenger bus in service between Asbury Park and Lakewood (50 miles), and Asbury Park and the Rumson Road (35 miles). Trips are made daily to these two points, and in some cases an additional trip is made to the Rumson Road.

The Royal Gray Line competes with the Rogers Line with three twenty to thirty-five passenger Mack machines, adding also a special trip to Bay Head at an increased fare of \$2.50 per passenger. The fare to Lakewood is \$2 per passenger, and to the Rumson Road \$1.50 per head.

The buses are also chartered to parties for special excursions.

The Silken Motor Company of New York has a number of town cars on hire at the leading hotels during the two months' season from July 1 to early September.

# Taxicabs on the Jersey Shore,

The New York Taxicab Company are now operating about two dozen taxicabs at their Elberon, N. J., branch, garaging them at the Sea Shore Garage. Most of their work is done in the evening, parties renting the cabs for runs to nearby country restaurants, as well as for attendance at social functions.

The Autocar Service Company, 403 Munroe avenue, Asbury, Park, N. J., have fifteen automobiles in the livery business, including taxicabs, station cars and touring cars. Rates to any address in Asbury Park are 25 cents per passenger. By the hour charges are as follows: Taxicab, \$3 per hour; waiting time, \$1.50 per hour. Station car, \$5 per hour; waiting time, \$2.50 per hour. Touring car, \$5 per hour; waiting time, \$2.50 per hour.

M. E. Sexton, a livery stable keeper of 401 Munroe avenue, Asbury Park, has also put in a few taxicabs recently and expects to purchase more of them.

# Commercial Notes.

The Imperial Valley Transportation Company, which was recently incorporated at Imperial, Cal., by F. C. Paulin, Geo. P. Blair and others, has placed an order for twelve nine passenger motor stages, of which the three first have already been received. In addition to carrying nine passengers the vehicles will carry a ton and

a half of freight, and the company will take orders from business houses on their run to the city and deliver the goods on the return trip. The company also intend to carry pupils to school.

G. C. Thaies, of Oxnard, Cal., has started a motor service between Nordhoff, Ventura and Oxnard with a high powered touring car. The train service between these points is said to leave much to be desired.

Automobiles will be used for the collection of mail at Los Angeles, Cal., according to a letter from the Postmaster General recently received by Postmaster Flint, of Los Angeles, if contracts can be let at reasonable terms.

The Eastern Auto Transit Company, Schenectady, N. Y., has placed an order for ten motor buses. The first of the cars was placed in service between Schenectady and Altamont on August 11. Three round trips are to be made every day.

An automobile stage line has been in augurated between Las Vegas and Santa Rosa, N. M. The cars which also carry the mail between Las Vegas and Anton Chico, Casaus and Colonias are said to be a marked improvement over the horse stage line.

T. J. Burrow, Jr., representing H. Thorpe & Co., of Jackson, Amador County, Cal., has let the contract for two White steamers for the Stockton-Jackson motor stage line. One of the cars is a seven passenger and the other a five passenger one. The service will be started immediately.

Lou Fox and Geo. Morris have decided to establish an automobile service between Nevada City and Sierra City, Cal. The company employs seven passenger touring cars, and its route includes the towns of North San Juan, Camptonville, Mountain House, Forest City, Alleghany, Goodyear Bar and Downieville.

The City Council of Redlands, Cal., has delegated its fire department committee to make an investigation of the motor fire engine question. The committee will make trips to Los Angeles, Hollywood and Long Beah to inspect the motor propelled fire vehicles there, and will then confer with builders of such vehicles. At a recent meeting of the council opinion seemed to be almost unanimous that no more horses should be bought for the fire service, as Redlands is a very hilly city, and a horse equipment is almost useless for fighting a fire on the heights, as it takes too long to get there.

The Plainfield (N. J.) Auto Bus Company, which was mentioned a number of times in our columns several months ago, has started its service between Plainfield, South Plainfield, Oak Tree and Metuchen. The roads along the route covered are all macadamized, and there are no railroad crossings. The buses which have been placed in service carry fourteen passengers each. The company will have two of these buses in regular operation and a third one in reserve for outings, etc. The officers of the company are: A. E. Force, president;

Wm. Newcorn, vice president; Fred A. Duttenhofer, secretary, and Isaac Schwed, treasurer.

# Rules and Plans of Atlanta Show Announced.

Applications for space and diagrams of the Atlanta National Automobile Show, Atlanta, Ga., November 6 to 13, 1909, under the management of Samuel A. Miles, general manager National Association of Automobile Manufacturers, and Alfred Reeves, general manager American Motor Car Manufacturers' Association, have been mailed to all makers of motor cars and accessories. The Southern show will be held in the Auditorium-Armory, which by the removal of various partitions gives the management 65,000 square feet of floor space.

Applications for space to be considered in the first allotment must be received at the headquarters of the National Association of Automobile Manufacturers, 7 East Forty-second street, New York, by Saturday, September 4. No application after that date will be considered until all applicants up to that time have been taken care of. The first allotment of space will take place at the office of the N. A. A. M. at 3 o'clock, Wednesday, September 8.

The Auditorium-Armory, where the exhibition will be held, is one of the largest exhibition buildings in the South. It is owned by the city of Atlanta and since its erection has been used for some of the largest conventions held in the South. During the automobile show the new automobile track now being constructed will be opened, and endurance contests through the various sections of Georgia will be held, with prizes for the best stretches of road, and a reliability trip from New York to the enterprising Southern city is being planned.

Working in conjunction with Messs. Miles and Reeves are Asa G. Candler, president of the Atlanta Chamber of Commerce; John S. Cohen, Clark Howell, E. W. Gans, S. C. Dobbs, C. R. Ryan, E. M. Hanson, J. T. Fitten and others.

# New Brush Factory.

Finding their present quarters inadequate to supply their growing trade, the Brush Runabout Company have decided to build a new factory in the northern part of Detroit. A large site has been purchased between Oakland avenue and the Grand Trunk R. R. The plans provide for a 636x 200 foot machine shop, a 150x80 foot office building, a 288x200 foot paint and finishing shop and a foundry and an experimental building.

### To Build 200 Moyer Cars.

H. A. Moyer, the well known carriage builder of Syracuse, N. Y., will manufacture a \$1,500 and a \$2,000 car, limiting himself to about 200 the first year, and marketing them through the agents who handle his carriages.

# Recent Decisions.

OUESTION FOR THE TURY.

The question as to the negligence of an employee using a motor car on a railroad track, where he was killed by a train following, was held to be one for the jury.-Yeandle vs. Pennsylvania R. R. Co., N. J. Cir. Ct. App.; 169 Fed. Rep., 938.

# CONTRIBUTORY NEGLIGENCE PREVENTS RE-COVERY.

In a collision between a street car and an automobile, it was held that a recovery could not be had where the auto ran against the street car, and the driver of the auto was held guilty of contributory negligence. -McCreery vs. United Rys. Co., Mo., 120 S. W., 24.

MISTAKE OF FLAGMAN SUSTAINS VERDICT.

The invitation of a flagman to the driver of an automobile to cross the railroad tracks, thereby causing his death, was held to be sufficient to sustain a verdict of \$7.000 damages for loss of life, which was held not excessive where plaintiff's intestate was thirty-five years of age and earning \$18 a week.-La Belle vs. Rhode Island Company, R. I., 73 Atl., 306.

#### Suggested Amendments to Ohio Law.

Fred H. Caley, Ohio State Registrar of Automobiles, announces that he will make recommendations for only two amendments to the present State automobile law when the next General Assembly convenes. It is believed that Ohio's law is almost perfect except in the two particulars which it is proposed to remedy. One of the amendments will permit an owner to transfer his license and set of tags from one motor car to another when he sells his first. This can be done through the State Department by the payment of a nominal fee. At present every car must be licensed by every one of its owners. The other amendment will provide for an examination for the licensing of chauffeurs. It is thought the amendments will be incorporated in the present law and that no other changes will be made.

### Supplementary Spiral Spring Patent Suit.

The Supplementary Spiral Spring Company, 4524 Delmar avenue, St. Louis, Mo., have filed a suit in the United States Circuit Court at New York city against M. H. Cormack & Co., Inc., and M. H. Cormack personally, of Motor Mart Building, 1876 Broadway, New York, for alleged infringement of their patents, Nos. 807,612, dated December 19, 1905, and 901,578, dated October 20, 1908.

M. H. Cormack was formerly the New

York representative of the Supplementary Spiral Spring Company, but some time ago severed his connection with that company and organized M. H. Cormack & Co., Inc., to manufacture spiral springs under license from J. H. Graham, of Boston, who claims to be the original inventor of supplementary spiral springs. Graham's patents are Nos. 503,044, 555,857 and 570,473, granted August 8, 1893; March 3, 1896, and November 3, 1896, respectively. Graham in his patent specifications described his invention as applicable to car trucks, but now claims that it covers application to automobiles as well. We are informed that an interference case is now pending in the United States Patent Office to determine this point.

### Road Hog Gets His Deserts.

Ernest Novak, a farmer of Racine County, Wis., was found guilty of maliciously obstructing and blockading a public highway and fined \$10 and costs in the Racine Municipal Court. The complaint was made by Henry Plow, of the Mitchell Motor Car Company, of Racine, who charged that on August 8. while returning from Milwaukee with a party of three ladies and his driver, Novak refused to permit him to pass and drove his horse in a manner that unduly blockaded the highway. A snail's pace was kept up for fifty-five minutes, a distance of only 5 miles being covered by both horse and touring car. Each time Mr. Plow attempted to pass Novak drove his horse across the highway. This is the first case of this kind to come before a Wisconsin court. The defendant has appealed to the Circuit Court.

# Alleged Abuse of New Jersey Non-Resident Exemption Provision.

The Atlantic City, N. J., Press prints an editorial in bold face type in which it asserts that the liberal provision of the New Jersey law permitting non-resident motorists to use the roads of the State for a limited period at a nominal cost is being abused by these motorists, and that the Legislature at its meeting next winter may be compelled to make certain changes in the law. The paper goes on to state that it has been found that tourists' licenses are frequently purchased by Philadelphia and New York people early in the season, and then used once or twice a week until each of the days of permission is cancelled. In this way the tourists can buy a ticket early in the season and go to a New Jersey resort each Sunday for two months and enjoy for \$1 the same privileges as others enjoy practically for the full license, which costs them

It is certainly not clear of what the alleged abuse consists, unless it is considered an abuse of the privilege granted by the law to leave New Jersey resorts after a stay of only one or two days. The law specifically provides that a non-resident holding one of these special licenses may use the roads of the State for four periods of two days each in one calendar year, or one period of eight days in one calendar year. It would seem from the above that the "four periods of two days each" privilege is objected to.

Sentenced for Robbing Garage. Robert Taintor, of Viroqua, Wis., a college student employed by the Holway Auto Garage, Fifth and State streets, La Crosse, Wis., as a helper, was sentenced to serve three years in the State reformatory for robbing the garage of \$50 and then setting fire to the office to cover the crime. The fire was extinguished before it reached the garage department.

# Legal Notes.

The automobile tax law which had been pending before the Georgia State Legislature for some time, and which imposed a tax of \$5 annually on automobile owners, has been killed.

The city of Kenosha, Wis., will adopt a "rules-of-the-road" ordinance at the next meeting of the common council. Since January I nearly all of the larger-cities of Wisconsin have adopted the code.

E. S. Esterly, a jeweler of Duluth, Minn., was recently fined \$10 for stationing his automobile in the street with a sign attached announcing that it was for hire, and refusing to remove it when ordered to do so by a patrolman. Esterly appealed the case to the District Court.

The position of chauffeur has been placed in the New York State non-competitive list by a civil resolution approved by Governor Hughes. The application for the exemption of the position was made by the State Highway Commission, which has recently bought four automobiles. The salary is \$100 a month. This is the first time the position has been recognized in the State service.

The County Board of Tax Equalization of Atlantic County, N. J., has discovered that not a single automobile or motor boat in Atlantic City is being taxed, although automobiles and motor boats to the estimated value of \$450,000 are owned in the city. None are mentioned in the assessment lists. It is proposed to put on additional assessors or assessors' clerks, and get every car in the city on the list.

# Contract for Ohio License Tags.

The automobile registration bureau of the Ohio Secretary of State's office will in the near future-probably in September-advertise for bids for 25,000 enameled number plates for automobiles. Last year the samples submitted were examined by Ohio State University as to their workmanship, lustre, solubility in water, solubility in dilute acid, effect on them of acid and acid gases, and the amount of bending or blows they would stand without cracking or breaking. It is presumed the same tests will be made this year.

# The Inaugural Races on the Indianapolis Speedway.

Several new track records, from I to 200 miles, were made at the three days' meet held on the Indianapolis Motor Speedway near Indianapolis, August 19-20-21. William A. Bourque, driver, and Harry Holcomb, his mechanic, both of Springfield, Mass., who had one of the Knox entries, were killed on the opening day of the meet, and three spectators were killed on the closing day.

The deaths of Bourque and Holcomb occurred during the 250 mile race on Thursday for the Prest-O-Lite trophy. The cause of the accident could not be determined, but witnesses said both men looked back and the car ran into an open ditch along the home stretch, turning over. Holcomb was thrown against a post and killed instantly. Bourque died within fifteen minutes.

There were rumors after the first accident that the 2½ mile course, upon which the events were run, was not in fit condition for the speed tests that were undertaken. On Friday morning officials of the A. A. A. made a trip around the track, ordered a few changes, and the ditch covered and gave sanction to the races.

There were rumors that the 300 mile race would be cut shorter, or that drivers would be changed, but it was decided to carry it out according to the program. In his 190th mile Charles Merz, a twenty-one year old boy driving a National, crashed into the fence, instantly killing William Kellogg, Benjamin Logan and H. H. Jolleffe, all of Indianapolis. Merz miraculously escaped with a few scratches, while his mechanician was probably fatally injured.

Directly after this accident Bruce Keene, driving a Marmon, crashed into the overhead bridge over the track. Keene and his mechanician were slightly hurt. It was seen the drivers were in no condition to continue, and in the ninety-fourth lap the A. A. A. officials called the race off. The leading car at that time was a Jackson, driven by Lynch, with De Palma in his Fiat second, and Stillman, driving a Marmon, third.

Only half of the 5 mile course has been completed. While the track in front of the grand stand and for some distance each way was oiled, the remainder of the track was covered with fine stone particles, which frequently broke the drivers' goggles and gave them intense pain. Chevrolet, driving a Buick, was obliged to get out of the 250 mile race because he was almost blinded.

The crowds at the races were all that could have been expected, about 12,000 attending the opening day, 22,000 on Friday and about 30,000 on Saturday. From a financial standpoint the meet was a success. It is understood another meet will be held next month or in October.

The results of the races for each day were as follows:

### THURSDAY.

Event No. 1—Five mile stripped chassis, Class 4, 161 to 230 cu. in. piston displacement: Schwitzer, driving Stoddard-Dayton, first; time, 5:13.4.

Wright, Stoddard-Dayton, second, and De Witt, driving Buick, third.

Event No. 2—Ten miles stripped chassis, Class 3, 231 to 300 cu. in. piston displacement: Chevrolet, driving Buick, first; time, 8:56.4. Strang, driving Buick, second, and Burman, driving Buick, third.

Event No. 3—Five mile stripped chassis, Class 2, 301 to 450 cu. in. piston displacement: Bourque, driving Knox, first; time, 4:45.5. Burman, driving Buick, second, and Chevrolet, driving Buick, third.

Event No. 4—Ten mile free tor all: Harroun, driving Marmon, first; time, 8:22.5. Lynch, driving Jackson, second, and Aitken, driving National, third

Event No. 5—250 mile stripped chassis, 301 to 450 cu. in. piston displacement: Burman, driving Buick, first; time, 4:33:57.4. Clemens, driving Stoddard-Dayton, second, and Merz, driving National. third.

Exhibition mile by Barney Oldfield, driving Benz, :43.1; fastest mile during meet, and breaking former circular track record of :48.2, held by Webb Jay.

#### FRIDAY.

Event No. 1—One mile trials: Oldfield, driving Benz, :43.1; Zengle, driving Chadwick, :49.3; De Palma, driving Fiat, :46.6.

Event No. 2—Five miles for cars of 231 to 300 cu. in. piston displacement: Strang, driving Buick, first; time, 4:48. Chevrolet, driving Buick, second, and Stutz, driving Marion, third.

Event No. 3—Ten mile stripped chassis, 301 to 450 cu. in. piston displacement: Merz, driving National, first; time, 9:16.3. Chevrolet, driving Buick, second, and De Hymel, driving Stoddard-Dayton, third.

Event No. 4—Ten miles for cars to compete for Wheeler & Schebler trophy, under 600 cu. in. piston displacement: Aitken, driving National, first; time, 9:26.6. Lytle, driving Apperson, second, and Heina, driving Lozier, third.

Event No. 5—Fifty mile stripped chassis, 161 to 230 cu. in. piston displacement: Wright, driving Stoddard-Dayton, first; time, 59:23.1. Schwitzer, driving Stoddard-Dayton, second.

Event No. 6—Ten mile, free for all, open, Class E: Zengle, driving Chadwick, first; time, 8:23.2; Aitken, driving National, second, and Ford, driving Stearns, third.

Event No. 7—Five mile, free for all handicap: Aitken, driving National, ten seconds handicap, first; time, 4:25. Merz, driving National, twenty seconds handicap, second, and Clemena, driving Stoddard-Dayton, thirty seconds handicap, third.

Event No. 8—100 miles stripped chassis, 231 to 300 cu. in. piston displacement, for G & J trophy: Strang, driving Buick, first; time, 1:32:48.5, breaking former record of 1:44 held by Burman, and made at Columbus, Ohio, July 3. De Witt, driving Buick, second, and Stillman, driving Marmon, third. The twenty, thirty, forty, fifty, sixty, seventy, eighty and ninety mile records were also broken during the race by Strang.

SATURDAY.

Event No. 1—Trials to lower kilometer record: Christie, driving Christie, :28.7; Zengle, driving Chadwick, :29.9; Oldfield, driving Benz, :26.2; the kilometer record is held by Chevrolet, and was made in :19 2-5 at Ormond Beach in a 200 h. p. Darracq, January 25, 1906.

Event No. 2—Fifteen miles free for all handicap: De Palma, driving Fiat, scratch, first; time, 13:23.5. Kincaid, driving National, handicap one minute and fifteen seconds, second, and De Witt, driving Buick, handicap two minutes and fifteen seconds, third.

Event No. 3—Twenty-five mile free for all for Remy Brassard and weekly salary of \$75 as long as winner holds title: Oldfield, driving Benz, first; time, 21:21.7, lowering five, ten, fifteen and twenty mile records, and twenty-five mile record of 23:25, held by De Palma.

Event No. 4—Ten miles for amateur championship of America: Hearne, driving a Fiat, first; time, 9:44.3. Ryall, driving Buick, second.

Event No. 5-300 mile stripped chassis, under 600 cu. in. piston displacement, for Indianapolis Motor Speedway Trophy, valued at \$7,500, donated by Wheeler & Schebler. Not finished.

# The Moline Protest Against the Award of the Hower Trophy.

After refraining from a discussion of the subject for the past few weeks, W. H. Van Der Voort, president of the Moline Automobile Company, has issued a statement concerning his protest against the awarding of the Hower trophy to the Pierce car in the recent Glidden Tour. Mr. Van Der Voort does not wish it to be thought that his protest was merely on the matter of carrying a tail light. He says in part:

"Noting that an erroneous report has gone out to the effect that Moline car, 101, was protesting the decision on the grounds of Pierce car, 108, not carrying a tail light, we feel that this impression should be corrected. Pierce car, 108, did carry its tail light, and my protest is based upon the fact that this tail lamp was completely demolished and the bracket considerably bent.

"Penalties were provided for deterioration, and according to the rules car 108 should have been penalized to the extent of the price of a new lamp and the labor required to straighten the tail lamp bracket. Moline car, 101, was required to light its oil lamps, proving condition. This would have been impossible with car 108, as the tail lamp was entirely inoperative.

"On the basis of material and labor in repairing the bracket, and replacing the lamp, it would alter the final score in my favor.

"I have no criticism whatever as to the findings of the committee upon penalties which were imposed upon Moline entry, 101, and while the crushing of the tail lamp and the bending of its bracket may appear trifling, I feel that the tightening of the three spring clip nuts, and the furnishing of one 1/4x1 inch cap screw, and one 1/4x1 inch step bolt, upon which our penalties were levied, are, from the operative standpoint, of very much less importance."

### Load Burned-Truck Saved.

A motor furniture delivery truck, belonging to R. J. Horner & Co., New York, caught fire as it was being driven out to Hastings-on-the-Hudson last Saturday morning. The driver was apprized of the fire by people looking and pointing at the truck, till he realized something must be wrong. He was driving at about 12 miles per hour at the time. The entire body back of the driver's seat, and the contents, consisting of about \$1,100 worth of furniture, were consumed, but the chassis was practically uninjured and was driven back to New York under its own power. It is supposed that the driver or the helper was smoking, and that the sparks from the cigar ignited the inflammable material with which the furniture was packed, but the driver denies this, and says he has no idea how the fire originated. The fact that the gasoline tank was intact and the chassis uninjured would seem to prove that the fire was in no way due to gasoline or anything about the mechanism of the truck.

# MINOR MENTION

The Hendee Manufacturing Company, Springfield, Mass., manufacturers of Indian motorcycles, have adopted the Bosch magneto for their 1910 output.

The Yuba Construction Company, Yuba City, Cal., who have been manufacturing dredging machinery, have decided to engage in the manufacture of automobiles.

The Johns-Manville Company, 100 William street, New York, furnish a fireproof, weatherproof siding, called Asbestoside, which they recommend as specially adapted to garages.

During the week ending August 14 the following cars led in the registrations in New Jersey: Oldsmobile, 11; Maxwell, 10; Ford, 9; Buick, 8; Reo and Cadillac, 6 each; Pope lines, 5.

The Darby Motor Car Company, St. Louis, Mo., has removed to 530-32 De Baliveire avenue, and will shortly begin the manufacture of the Darby car on an increased scale.

Howard W. Brown, of the Binghamton (N. Y.) Motor Car Company, plans to establish a wholesale supply business in connection with his new garage, which will be completed some time next winter.

The Milwaukee Prest-O-Lite Company has been formed in Milwaukee, Wis., and headquarters have been established at 192 Fifth street. Walter L. Ebert is manager. A recharging station has been installed.

At the plant of the E-M-F Company in Port Huron, Mich., nearly 300 men are employed at the present time, and arrangements are being made for erecting a large power plant in connection with the factory.

The Middletown (Ohio) Buggy Company will take up the manufacture of motor delivery wagons on September 1. Much new machinery has recently been installed, and considerable capital will be invested in the new venture.

The executive officers of the Studebaker Automobile Company will shortly be transferred from Cleveland to South Bend, Ind. The personnel of the organization remains the same. The company will maintain its Ohio branch in Cleveland.

John S. Taylor, of Logansport, Ind., has invented a vehicle hub which is said to be absolutely dustproof and impossible to come off the axle. Mr. Taylor is at present in Spokane, Wash., and may organize a company there to manufacture his hub.

The American Napier Automobile Company is at present preparing at its Jamaica Plain, Mass., factory for the manufacture of 200 town cars. The factory will be in charge of H. Kerr Thomas. S. F. Edge is at present in this country assisting in getting the work under way, and it is stated that both Mr. Edge and Mr. Napier will spend part of each year at the American

factory superintending the business and mechanical operations respectively.

The Prest-O-Lite Gas Company, Los Angeles, Cal., have purchased a 100x200 foot plot on the south side of Lacy street, near Avenue 26, on which they will erect a building to serve as a recharging plant for Prest-O-Lite gas tanks.

John H. Kelly, of Chicago, has been appointed trustee of the Chicago Vulcanizing Company to conserve the assets and continue the business for the benefit of creditors. An inventory of the assets is now being taken, and a statement will be sent to all creditors in the near future.

It is predicted that Cleveland's automobile centre will within another year be established on lower East Ninth street, north of Superior avenue Northwest. Most of the sales establishments in the city are now located on Euclid avenue, but rents there, in the vicinity of the shopping district, are constantly rising.

Thomas Forbes, a former Minneapolis insurance agent, has invented a revolving cylinder gasoline motor, and is organizing the Los Angeles Rotary Engine Company in Los Angeles, Cal., for its exploitation. The engine has five radial air cooled cylinders which revolve around a central stationary crank shaft.

According to a report from Harrisburg, Pa., the authorities of that State are convinced that macadam roads are quickly destroyed by automobile traffic, and they plan to pave the roads with firebrick in the future. This form of road would be quite expensive in the first place, but would cost little to keep in repair.

The National Motor Supply Company has been organized at Cleveland, Ohio, with a capital stock of \$10,000, to manufacture a variety of automobile and motor boat supplies, principally steam vulcanizers and gasoline gauges. V. H. Meyer, who was formerly connected with the B. F. Goodrich Company, of Akron, Ohio, will be manager.

The Maxwell-Briscoe Motor Vehicle Company, of St. Louis, Mo., will open an accessories branch in connection with their downtown salesroom at an early date. M. W. Doyle, formerly in charge of the accessories department of the Buick Motor Company, will have charge of the new department. A complete line of supplies will be carried.

The supply dealers and jobbers of Kansas City, Mo., held a meeting on August 12 at the Coates House to take preliminary steps toward the organization of a local dealer's association. It seems that, the same as in other cities, the fact that certain jobbers also do a retail business has created more or less friction with firms who do a retail business only.

During the week ending August 14 the following cars headed the list of registrations in New York State: Ford, 41; Maxwell, 29; Cadillac, 27; Buick, 25; E-M-F, 19; Packard, 19; Reo, 15; Overland, 12; Stevens-Duryea, 11; Franklin, 10; Olds, Winton and Palmer & Singer, 9 each; Auto-

car, Locomobile and Peerless, 8 each; Rambler, Mitchell and Stoddard-Dayton, 7 each.

During the month of July, 1909, there were imported at the port of New York by dealers 82 pleasure cars, 38 taxicabs and 1 motor truck, aside from 45 old cars imported by individual owners, and 8 new cars. Of the 82 pleasure cars imported by dealers, 22 were Fiat, 20 Renault, 9 Mercedes, 9 Delaunay-Belleville, 8 Benz, 3 Hotchkiss and 3 De Dion, and of the 38 taxicabs imported, 17 were Renault, 10 Lancia and 10 Fiat.

Edward C. Huhn, Philadelphia manager of the Puritan Soap Company, of Rochester, N. Y., recommends that for washing cars 20 pounds of soap be dissolved in 25 gallons of water, and this solution used with water as occasion demands. He asserts that this will result in a saving of 25 per cent. in the soap bills of garages and automobile companies, as compared with where large pieces of soap are used on a sponge for making a lather.

The old Guttenberg race track at Guttenberg, N. J., where one of the first automobile races in the country was held in 1900, has passed under the control of the Palisades Amusement Company, and an inaugural meeting will be held on the track on Labor Day, September 6, the feature being a 300 mile race. A twenty-four hour race is planned for September 11. The track consists of a mile oval, with a straightaway course, but it is to be enlarged into a 2 mile circuit.

So many automobiles use the ferry across Long Island Sound, between Rye and Sea Cliff, that the ferryboat Englewood, which was chartered from the Fort Lee Ferry Company, has proven entirely inadequate, and the Oakland Steamboat Company, the owners of the ferry service, have just placed an order for a new two propeller double end ferryboat, which will carry at least fifty automobiles. Work on the boat will be begun in October, and it will be ready for service early next spring.

A. Frederick Collins is conducting some experiments to determine the availability of wireless telephoning for automobilists in communicating with a garage or a relief station. So far the results have been rather unsatisfactory. Mr. Collins was able to communicate over a short distance with a garage in Newark, N. J., but at a distance of 8 miles the apparatus failed. The difficulty is said to be due to the fact that only short antennæ can be used, and a great amount of energy must be expended to transmit the signal only a short distance,

It is reported that a number of the large Eastern railroads, including the Baltimore & Ohio and the Pennsylvania, are being equipped with special baggage cars for the accommodation of wealthy automobilists who wish to take their cars with them to distant parts of the country. These baggage cars are provided with a door in the end of sufficient width to permit of the entrance of a large touring car. In loading the cars the automobiles are placed on

skids and run into the end before the auto coach is coupled to the train. It is said that the New York Central has also ordered fifty of these auto baggage cars.

The Jewel Company, Carthage, Ohio, are to turn out a \$1,500 car for 1910.

The Auto Supply Company, 1326 Vine street, Philadelphia, have secured the agency for Home tires, made in Trenton, N. J.

The Federal tire is now represented in Philadelphia by the Auto Exchange, at 1437 Vine street, who have the exclusive agency for Pennsylvania.

The Deranie Motor Company, 7500 Quincy avenue, Cleveland, Ohio, will build this season twenty-five \$4,000 cars, equipped with two cycle motors.

The Selden Car Company of Pennsylvania opened show rooms at 352 North Broad street, Philadelphia during the past week, and handle the Selden car.

The Empire Tire Company, of Trenton, N. J., has opened a direct branch, corner Broad and Woods streets, Philadelphia. The branch is in charge of E. B. Richardson.

The Apperson car which recently established a new speed record in California, covering 202 miles at an average speed of 64.45 miles per hour, was fitted with New Departure ball bearings.

The Coppock Motor Car Company, of Decaur, Ind., will issue \$100,000 worth of 6 per cent. bonds, giving bondholders the privilege of exchanging the bonds for stock within eighteen months after the date of issue.

Employees of the Mitchell Motor Car Company, Racine Manufacturing Company, Pierce Motor Car Company and Piggins Brothers Company, of Racine, Wis., and Thomas B. Jeffery & Co., of Kenosha, Wis., held their first annual joint picnic at Central Park, Racine, on August 22.

Ben Loy, a racing driver, was killed on the Cheyenne motor race track on August 14, owing to a collision between his racing car and a cow. His mechanic, Shannon Lees, was also thrown out of the car, and had to be taken to a hospital, but his injuries are said to be not serious. Loy was employed by R. J. McCarthy, of Denver, Col.

The Auto Sales Company has been organized at Appleton, Wis., by a number of business men to sell motor vehicles, equipment, supplies and accessories in the Fox River valley. The company has contracted for the agency for the Kisselkar in that territory. Herman G. Saecker is president, J. L. Wolf vice president, P. M. Conkey secretary, Samuel J. Ryan treasurer.

The Badger Automobile Company, of Columbus, Wis., has started work on the erection of its factory. The building will have dimensions of 50x150 feet, two stories high, of solid brick construction. The entire floor space will be unobstructed, excepting for walls of the various department rooms. The Milwaukee road has afforded sidetrack fa-

cilities direct to the shops. The company expects to occupy the factory about November I.

#### Club Notes.

The Cornwallis A. C. is to be organized at Cornwallis, Ore., where quite a number of machines have been sold recently. The movement is being promoted by S. L. Kline.

Automobile owners of East St. Louis, Ill., held a meeting at the Elks Club rooms on August 13, with the object of organizing an automobile club. The object of organization is to suppress speeding in the locality and to join the State Association.

Automobile owners of Abilene, Kan., organized an automobile club at a meeting held on August 9. The following officers were elected: C. M. Harger, president; E. H. Forney, vice president, and J. T. Nicolay, secretary and treasurer.

The Lake Placid Club, Lake Placid, N. Y., is building a garage that will accommodate sixteen automobiles. This is an addition to a smaller garage, accommodating eight machines, that was erected several years ago. The new garage will have a cement floor, a repair shop and a pit.

The Automobile Club of New Rochelle, N. Y., was organized at a meeting held on August 20, with a charter membership of fifty. E. T. Birdsall was elected president, W. B. Ogden first vice president, J. A. Scofield second vice president, F. M. Carpenter secretary, and F. D. LeCount treasurer. It is said that there are 250 owners in the city.

To Wind Up Grout Automobile Company.

Receivers E. S. Hall and David Walsh, of the Grout Brothers Automobile Company, Orange, Mass., have petitioned the Superior Court for permission to sell the plant and to be released from the receivership. They were appointed by Judge Hitchcock in July, 1907.

# Garage Notes.

The Eastern Motor Car Co., Los Angeles, Cal., will shortly move into their new garage on South Olive street.

The Los Angeles, Cal., Stoddard-Dayton Motor Co. has moved into its new garage at Tenth and Olive streets.

Holloway & Patterson, district agents for the Buick at Janesville, Wis., now occupy their new garage. The firm has ordered fifty 1910 models. Chas. H. Thompson, who handles the Jackson

Chas. H. Thompson, who handles the Jackson car in Los Angeles, Cal., has moved to new quarters at 1012 South Main street, vacated by the Stoddard-Dayton Motor Co.

The Lucia Cycle Co., of Green Bay, Wis., agent for the Thomas and Chalmers-Detroit and Hudson, has moved into its new garage. The company is establishing branches throughout northeastern Wisconsin.

E. J. Hahn, Aurora, Ill., will erect a two story garage and machine shop building. It will have a 30 foot frontage on West Second street. Mr. Hahn has been engaged in the auto repair business for some time, and has outgrown his present quarters.

The capital stock of the H. O. Harrison Co., Peerless agents in San Francisco and Los Angeles, has been increased from \$50,000 to \$100,000. The original allotment of 1910 cars for the two Harrison companies was seventy-five, but this was later increased to ninety, as the prospects for 1910 business on the Pacific Coast are said to be particularly bright.

The Cartercar Co., of Pontiac, Mich., have opened a sales office in Wichita, Kan., at 115 to 119 East Second street, in charge of F. P. Kreikenbaum, who formerly had charge of the company's Chicago salesroom.

Plummer Eaton and Howard Humes, of Tarentum, Pa., have formed a partnership, and will erect a garage on Second avenue, comprising also a repair shop. The new firm will handle the Hupmobile, Chalmers-Detroit and Hudson Twenty.

Henry G. Goosman has purchased a garage building at 215 and 217 Eighth street South, Minneapolis, Minn. The building is 55x200 feet, two stories high, and completely equipped for automobile repair work. Mr. Goosman handles the Speedwell car and does a general automobile repair business.

#### Trade Personals.

- P. A. Williams, Jr., sales manager of the Atlas Motor Car Co., Springfield, Mass., sailed for Bermuda on August 18, and expects to also visit Porto Rico.
- C. E. Reddig, who was formerly in the engineering department of the Electric Vehicle Co., Hartford, Conn., has been appointed assistant engineer of the Columbia Motor Car Co., successors to the Electric Vehicle Co.
- C. A. Erickson, recently with the American Locomotive Automobile Co., Providence, R. I., and formerly with the Electric Vehicle Co., of Hartford, Conn., is now chief draughtsman of the Palmer & Singer Manufacturing Co., New York.
- C. T. Paxon has been appointed manager of the newly established Chicago branch of the E. R. Thomas Motor Co. Mr. Paxon has been connected with the Thomas Co. since its organization, and managed the local sales department in Buffalo since 1904.
- since 1904.

  E. W. Carter, who has for some time past been in charge of the Boston office of the Hoyt Electrical Instrument Works, will hereafter be connected with the factory at Penacook, N. H., and A. K. Brown will succeed him in charge of the Boston office.
- F. G. Baender and P. S. Biegler, both of Iowa City, Ia., have recently moved to Spokane, Wash., where they will shortly open an agency for the White steamer. Messrs. Baender and Biegler formerly were instructors in mechanical and electrical engineering in the University of Iowa.

Fred Titus, for some years head salesman for the Harry S. Houpt Co., has just made an alliance with the sales force of the Palmer & Singer Manufacturing Co., and on September I will begin his new duties in the capacity of assistant sales manager in charge of out of town territory.

Charles F. Pougher, M. I. A. E., has resigned as manager, designer and organizer of the Simms Magneto Co. and the Simms Manufacturing Co., Ltd., London. Mr. Pougher was formerly works superintendent of the Birmingham Small Arms Co., Ltd., Birmingham, and designed the Enfield cars, which are well known in England.

New Incorporations.

The Citizens Automobile Co., Birmingham, Ala.—Capital stock, \$25,000. Incorporators, J. C. Turner, M. F. Hickman, H. G. Robinson and G. W. Yancey.

Bridge Web Tire Co. of Illinois, Chicago, Ill.—Capital, \$2,500. Incorporators, F. H. Drury, S. Lewis and E. H. Clegg.

South Texas Automobile Agency, Falls City, Tex.—Capital, \$3,000. Incorporators, C. D. Jauer, Hugh Knight and J. H. Sims.

Scott-Harris Engine and Transmission Co., Chicago, Ill.—Capital stock, \$100,000. Incorporators, P. Steele, S. M. Thein and R. W. Waugh.

Cornell Auto Salesroom, Los Angeles, Cal.— Capital stock, \$25,000. Incorporators, C. F. Grundy, Fred A. Cornell and J. R. Grundy.

Studebaker Colorado Vehicle Co., Denver, Col.—Capital stock, \$100,000. Incorporatora, W. S. Hunnewell, W. Scott Bicksler and Jesse M. Wheelock.

# Babbitt Bearings.

BY S. M. UDALE.

I-ALLOYS.

The original alloy known as Babbitt metal was made of:

25 parts of tim, = 90.9 per cent. Sn. 2 parts of antimony, = 7.28 per cent. Sb. 2 part of copper, = 1.82 per cent. Cu. Thurston's "Alloys," Vol. III.

The name babbitt is now applied in America to a certain range of white antifriction metals. When the antimony is melted with an equal proportion of copper the babbitt is soft; when the antimony exceeds the copper, as in the original recipe, hard babbitt results. Antimony is a highly crystalline and very brittle metal which has the property of expanding on solidification. It imparts these properties to its alloys to a certain extent.

The latter property is of importance when casting a bearing in situ around the shaft or around a mandril substituted for the shaft.

Antimony will not oxidize in air. It burns, however, when heated, but the temperature in the ordinary bearing is seldom high enough for this.

> Antimony melts at 450° C. Tin melts at 228° C. Copper melts at 1,090° C.

It is to be noted that tin, which is present in by far the largest proportion of the three components in babbitt metal, melts at the lowest temperature. It is, although tin, ductile at ordinary temperature and may be cut with a knife; becomes brittle just before melting. This explains in part the slightly yellowish color of a burnt-out bearing—the copper not melting—and its brittleness. The white metal splashed all over the crank case upon the cam shaft, and under the piston, consists chiefly, if not entirely, of tin.

The coefficients of heat expansion of the component metals of babbitt are from 50 per cent. to 100 per cent. higher than the coefficient of heat expansion of steel, hence a side clearance of 0.005 is desirable, and the babbitt in the upper and the lower halves of the crank and main bearings should not touch, nor should the shims between the halves touch, the babbitt.

To illustrate the range of tin-antimonycopper alloys in actual use the following examples are given:

Name or Use,	Parts by Weight.								
	Tin.	Antimony.	Cop	per.					
	66,7	11.1	22.2	(8)					
English R. Rs	90	7	3	(0)					
(	85	10	.5	(d)					
French S. Rs	71	24	5	(e)					
Kamarsch	88.9	7.4	3,7	(5)					
	70	20	10	(E)					

It appears from the above that the tendency is to increase the proportion of antimony above that of the original babbitt to enable the bearing to carry a high load per square inch. Up to 2,000 pounds per square inch may be carried, but at the high speeds of automobile practice such loads are hardly safe for normal running. Other white metals suitable for use as bearings are:

Tin. Copper, +
White metal (zinc) .... 29,3 4.2 66.5% Zn, (4)
Nickel white metal.... 24,5 50 25,5 % Ni. (f)

The nickel alloys are used for the main bearings of two cycle engines having compression in the crank chamber. Such bearings are intended to wear like bronze or gun metal, so that little or no allowance need be made for taking up. Such a bearing is difficult to repair and it is better to replace it when worn. It wears a long time, however.

Lead babbitt is cheaper than the genuine article, but should be avoided. Being soft, the oil channels get clogged and lubrication is reduced in consequence, which is followed very quickly by a burnt-out bearing. Lead melts at 330° C., which is considerably higher than the melting point of tin, but the melting point of an alloy is not the arithmetic mean of the melting points of the component parts, taking into consideration the proportions in which they are present. This is well illustrated by the following example: Lead melts at 330° C., tin at 228° C., but an alloy containing 311/2 per cent. lead and 681/2 per cent. tin melts at 181° C. The variation of the melting point with the proportions of the components in the binary tin-lead alloy' is shown in Fig. 1.

Similar diagrams can be drawn for ternary alloys such as babbitt metal, only they are complicated and more difficult of interpretation. However, these "eutectics" are the key to the study of alloys. If a microscopic photograph be taken of a 30 per cent. tin and 70 per cent. lead alloy, small particles of lead are seen in a matrix of eutectic. In an alloy of 30 per cent, lead and 70 per cent, tin particles of tin are seen in a matrix of the same eutectic.

The theory of M. Charpy on the properties of anti-friction bearing metals is that the conditions demand that the material of the bearing should be both hard and plastic, which is impossible with a homogeneous alloy. (Homogeneous alloys are called solid solution.) Now, it so happens that the matrices (i. e., the eutectics) of these anti-friction alloys are softer than the precipitated particles. Hence they fulfill the requirements.

#### THE TRIANGLE DIAGRAM.

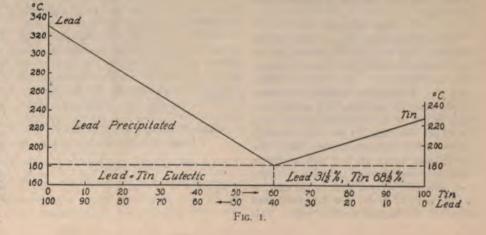

The study of the ternary alloys was much simplified by the use of a geometrical property of equilateral triangles. If from any point in an equilateral triangle, a b c, lines are drawn to the apices there are three triangles, a o c, o c b, and o b a, together equal to a b c. Triangles on the same base have areas proportional to their altitudes, hence:

a w = o x + o y = o z. And by similar triangles: a c = o c + o f + o g = a b = b c.

Hence every ternary alloy can be graphically represented by a point in the triangle. The alloys mentioned above are located

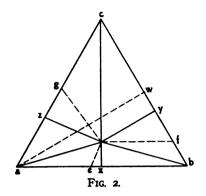

by this method on Fig. 3.

In Fig. 3 a' represents a babbitt metal formula, given in Unwin's "Machine Design," 1906 edition, and it is of interest to observe that a line joining a to a' includes

most of the babbitts suitable for automobile use.

An alloy identical with (f) is given in Kent as high duty babbitt. In experimenting with various proportions it is advisable not

to deviate much from the alloys represented by the line a-a'.

#### MANUFACTURE OF BABBITT.

Babbitt of a desired composition cannot be prepared by simply taking the three metals, tin, antimony and copper, in their predetermined proportions and melting them together.

The method generally adopted (Thurston's "Alloys," Vol. III) is as follows: To 12 parts of tin add 8 parts of antimony (regular) and melt together. Then add another 12 parts of tin. The pot is then removed from the fire and 4 parts of copper are added. This alloy is frequently sold in this form, but it is extremely brittle. One part of the alloy is therefore added to two parts of tin to prepare ordinary babbitt. This is the explanation of the "2 to 1" marked on babbitt bars.

Neglecting the oxidation loss of antimony and tin, the proportions thus obtained are:

```
12+12+72 parts of tin...... =88.9 per cent. of Sn.
8 parts of antimony. = 7.4 per cent. of Sb.
4 parts of copper.... = 8.7 per cent. of Cu.
=88.8 per cent. of Cu.
=88.9 per cent. of Sb.
= 4.0 per cent. of Cu.
```

Kent describes a process in which the reverse order is followed, the copper being first melted (12 parts), then tin added (36 parts), then antimony (24 parts), and finally 36 parts of tin. The heat is reduced when the copper is melted, and the surface is protected from the air to prevent undue oxidation of the antimony and tin. Fifty parts of this alloy are finally remelted with 100 of tin.

### LEAD ALLOYS.

Lead and antimony alloy together in any proportion, but the alloy containing 13 per cent. antimony melts at the lowest temperature, and hence is known as the eutectic (Fig 1). If the alloy contains more than 13 per cent. of antimony the excess antimony is present as crystallites embedded in the 87 per cent. lead. 13 per cent, antimony matrix, which is comparatively soft. The anti-friction alloys of lead and antimony, therefore, range from 15 per cent. to 25 per cent, antimony alloyed with 85 per cent. to 75 per cent. of lead. The last mentioned by has the highest melting point. This

alloy is quite a little cheaper than babbitt. The above explanation is due to M. Charpy. Lead babbitt is usually a normal babbitt, with half the tin replaced by the cheaper metal lead, e. g.:

Tin 45.5 per cent. + Lead 40 per cent. ⇒ 5.5 per cent.

Copper ..... = 1.5 per cent.

Antimony ..... = 18.0 per cent.

There are no simple geometrical diagrams to illustrate alloys made of four metals, and the amount of research work that has been done along this line is small. One objection to lead is that it is acted upon by oleic oils, that is, oils made from animal and vegetable fats. But as mineral oils are almost universally used this is not a serious matter.

The heat conductivity of lead is low, as compared with that of tin, and this is also a reason for not using lead. However, lead alloys have been successfully used for bearings in railway practice, but not for driving boxes. If sufficient area can be given to a bearing such alloys will show advantages over all others. In an automobile space is limited and the speeds are high, and babbitt is preferred.

PROPERTIES OF ANTI-FRICTION METAL BEAR-INGS.

First as to friction. The coefficient of friction depends only indirectly on the nature of the metals. It depends primarily on the nature of the lubricant, the supply and the temperature. If the metal of the bearing is soft the oil passages become restricted and thus affect the friction. White metal (babbitt, etc.) bearings run at a higher temperature than bronze bearings because (a) the metal is not continuous, and the heat has to be transferred from the

babbitt to the drop forged cap. The back of the babbitt is frequently not clean and the thermal resistance is thus much higher than it need be. In this connection cooling ribs should be placed both on the boxes themselves and on the crank case to radiate and conduct the heat away as quickly as possible. (b) The relative conductivity of babbitt is about one-half of that of bronze, hence the temperature drop in the thickness of metal separating the babbitt from the cap is twice as great for the same flow of heat as with a bronze bearing containing a large percentage of copper.

The bronze bearings are usually solid, but the connecting rod caps of automobile engines are of iron, which has exactly onesixth the conductivity of copper and onequarter the conductivity of bronze. Then, as mentioned above, there is the lack of continuity in the metals.

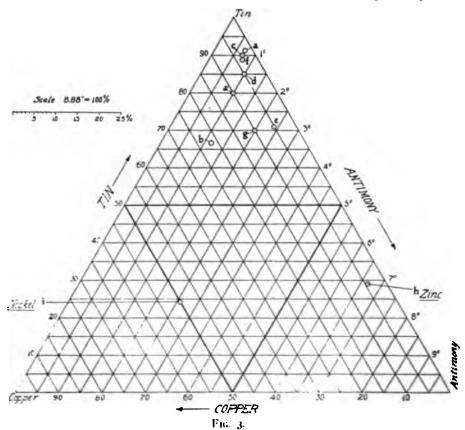

Aluminum caps, which are sometimes used on the main bearings, have twice the conductivity of iron ones. (c) The coefficient of friction of the metals has some slight effect, although the viscosity of the lubricant is of more importance. The following table gives the results of some comparative tests between babbitt and bronze in this respect:

	Bronze.	Babbitt.
Temperature	133° F.	1 <b>52°</b> F.
Coefficient of friction	0.010	0.013
Oil per hour, in oz	7	17

Thurston's "Friction and Lost Work."

As the same oil was used and the shafts were run at the same speed, it follows that any difference in the effects must be due to the metals.

The wear of the bearing takes place on

# The Economics of Motoring.

BY ALBERT L. CLOUGH.

the off side, and hence the lubricant should be fed in on the "on" side. With perfect lubrication there is an oil film of from 0.0005 inch to 0.001 inch, and hence there should be a diametrical clearance of from 0.001 inch to 0.002 inch. The wear depends on this clearance, but as the cap gets hotter than the crank shaft (as a rule) there is a certain amount of clearance due to expansion. Again, bronze and babbitt expand about twice as much as iron; a bronze bearing being solid, it is free to expand, whereas the babbitt in a bearing is not. Five-onethousandths of an inch end clearance should be allowed, as side wear is very likely to cause local overheating and thus start the metal to "burn."

Bearings for automobiles should be set up so that they can be moved laterally by one hand after being tapped with a lead hammer somewhat vigorously.

The wear on the bearings depends largely on the purity of the alloys, and special precautions should be taken to free the molten mass of metal from impurities. Fluxing with phosphorus is one means used for this purpose with bronzes.

With light oil lubrication there is a danger of having the crank pins so smooth that the oil film is never continuous. Where steel bears on steel the polish cannot be too high, but where steel bears on softer metals slight tool marks are an advantage.

Quantitative tests on wear are rare, and hence the following (locomotive) test is of interest:

Now that the motor car is being taken up, in a serious manner, by the moderately well to do classes, the economic side is being considered more than ever before, as bearing upon the type and class of car to be into account especially the use to which a automobile business as in human relationalmost as tragic. The effect of example is friend's requirements may be entirely different from those of the intending purway comparable.

In the ownership of an automobile two distinct sources of expense are met with,

purchased. There unquestionably ought always to be a close consideration upon the part of these intending purchasers, taking car is to be put, with the aim of making a choice which shall be satisfactory from the financial side. However, cars are often bought without any adequate deliberation of this kind. The intending purchaser is often captivated by some special point of a particular car, as explained by an able agent, and a purchase is made with little reference to the "main chance." Love at first sight is just as common a phenomenon in the ships, and its results are, on a small scale, also very strong. If a friend buys a certain make of car a strong incentive to purchase the same make is created, although the chaser, and his financial status may be in no

PERSON	PATTROPO	OT	PUREN	TOW

Babbitt I	4.	3	90	7	32,75	22	5.23
Babbitt 2		5	85	10	32.25	25	4.06
Lead Antimony,	84	**	25	16	13.00	23	4.40
				Thurs	ton's " Fric	tion and Lo	st Work."

Of course the figures for the cost of the metals vary greatly. They are intended to include cost of alloying, casting, etc.

One of the misleading properties of bearings is that the starting resistance is not always an indication of the permanent conditions of the bearings, but may be due simply to a temporary deficiency of lubrication. The practical application of this is that when a car has been standing with engine stalled for any time there is danger in immediately putting on a full load.

The German motor truck manufacturers are at present following the plan of establishing service corporations operating their trucks in the larger cities of the empire. Thus the Daimler Motor Company, of Marienfelde, has recently established such corporations in Breslau and Konigsberg, which start operations with five trucks each. The North German Automobile and Motor Company has also started a service with five trucks in Breslau, and E. Nacke, of Coswig, has organized a company to operate his trucks in the Kingdom of Saxony.

namely, the fixed charges and the operative charges. The former are inevitable concomitants of the possession of a car, and are but slightly dependent upon the extent to which it is used or how it is used (within reason). Most of the items which make up this class of expense are still incurred, whether or not the car is used at all, so long as it is in a person's possession in a condition ready for service.

The operative charge or the expense of operation is nil so long as the car is not used, and increases approximately with the extent to which the car is run. When the sum of the fixed charge and of the operative charge is a minimum for any particular period of service, the total cost of operation for that particular period is obviously a minimum, and when the sum of these two factors, per unit, of distance run, is at its lowest, the service thus obtained is secured at the least possible cost.

### FIXED CHARGES.

The fixed charge includes the income which the money invested in the car and its appurtenances would bring if it were invested in such a manner as to bear interest; the decrease in value of the car, or depreciation, which is mainly a matter of elapsed time alone, but which is somewhat dependent upon the extent and manner of use of the car; the cost of storage; the expense of fire and liability insurance upon it; the wages of a chauffeur if one is regularly kept; and taxes and license fees.

The operative charge includes the cost of fuel and oil and of ignition current, lights and tires. It also includes the cost of washing and polishing, and of tires, repair parts and labor expended in making adjustments and repairs.

Not all prospective owners of cars take the trouble to figure the inevitable expense in fixed charges which they are incurring in buying their cars, nor do they consider how much the fixed charge per annum is affected by the selections which they make, The bearing of the fixed charge upon the per mile of service required is too seldom regarded. As an example, two touring cars, one costing \$4,500 and the other \$1,500, fully equipped, may be taken. There is a fairly general agreement that 20 per cent. per annum represents the average rate of depreciation of a motor car, so far as its selling value is concerned, but there are those who believe that low priced cars depreciate more rapidly than those of high price, so 20 per cent, will be assumed in the case of the former and 25 per cent. in that of the latter. Interest on the investment will be taken on a 6 per cent, rate,

In the following two columns are enumerated several items which go to make up the fixed charge, the first column referring to the high priced and the second to the low priced vehicle:

	(1.)	(2.)
Interest on the investment	\$270.00	\$90.00
Depreciation	900.00	375.00
Storage	120.00	120,00
Fire insurance	112.50	45.00
Liability insurance	70.00	43.00

Totals .....\$1,472.50 If taxes are paid they are likely to be in proportion to the costs of the vehicles upon which they are assessed. As the high priced car may be assumed to be more powerful than the low priced one, the rate of registration will, in many States, be somewhat larger upon the former than upon the latter vehicle. The salary of a chauffeur is also more likely to constitute an additional item in the fixed charge upon the "swell" and powerful high priced car than upon the lower priced vehicle.

In the case of No. 1 (the high cost car) the fixed charge amounts to \$4.03 per day, and for No. 2 (the low priced vehicle) \$1.84 per day. This charge is inevitable, whether the car is used or not. If the rate of depreciation of the low priced vehicle were to be taken at the same rate as that of the high priced car its fixed charge cost per day would become \$1.64 instead of \$1.84. The figure \$1.84 will, however, be retained

#### FIXED CHARGE PER MILE.

It is at least interesting to note that, assuming gasoline to cost 15 cents per gallon, and that car No. 1 gives a mileage of 11 miles per gallon, while car No. 2 travels 15 miles per gallon, the daily fixed charge is equivalent to the fuel cost for 295 miles of driving, in the case of car No. 1, and for 184 miles of driving in the case of car No. 2.

As the fixed annual charge imposed upon the owner of a car is independent of the amount of service which the car performs, the greater the mileage traveled by the vehicle the lower will be the per mile fixed charge. Very few cars are used less than 2,000 miles per year, and not a large proportion more than 10,000 miles per annum, and these two figures serve well as extreme examples.

Car No. 1 if used 2,000 miles per year will show a per mile fixed charge of 73.6 cents, and if used 10,000 miles, of 14.7 cents.

In the case of car No. 2 the per mile fixed charges are, respectively, 33.6 cents and 6.7 cents.

The above figures admirably demonstrate a perfectly obvious though little heeded fact, that if a motor pleasure vehicle is to be operated with any sort of economy from the standpoint of service rendered it must be very largely used. It is hardly too much to say, with only slight exaggeration, that it should be kept going all the time.

As a piece of expensive machinery the automobile has few counterparts as regards the small proportion of its life during which it is actually rendering the service for which it is constructed. A pleasure vehicle which covers 10,000 miles is actually running during only about 666 hours of the 8,760 hours in the year, or about 71/2 per cent. of the time. The great majority of all other pieces of machinery of the same grade are in actual operation at least 2,700 hours per annum, or 30 per cent. of the time. The average pleasure car making 5,000 miles per annum is thus in active use only about one-eighth as much of the time as the generality of high grade machinery. It is not strange, therefore, that the fixed charge per unit of service rendered is enormously large. The pleasure car is too much like a machine which is "shut down" seveneighths of the time.

ANNUAL MILEAGE A FACTOR IN CAR SELECTION.

There is one point that can here be made which should appeal to the prospective buyer who is inclined to view the matter from the economic standpoint, namely, unless the buyer's requirements include a large annual mileage it will prove a very expensive matter for him to purchase a high cost vehicle. If only a small annual mileage is to be covered the fixed charge per mile will inevitably form a large part of the

sle charge per mile, and if a high priced

car is purchased the fixed charge per mile will not only form an excessively large part of the total but will be exorbitantly large. If a person motors but a couple of thousand miles a year, as many do, he is paying high for his pleasure if he buys a high priced car for this very limited service. As previously stated, 73.6 cents and 33.6 cents represent the fixed charges per mile on a 2,000 mile per annum basis, for the high and low priced vehicles here assumed.

If, on the other hand, a person requires extremely extensive service of a car, he can much better afford to buy an expensive vehicle, for his fixed charge per mile becomes a very much less important part of the total per mile expense, and the increase in its absolute magnitude becomes far less important, so much so, perhaps, as to be more than counterbalanced by the satisfaction to be derived from owning a swell car with large reserve of power and luxurious qualities.

#### HIGH PRICED CARS FOR HARD USERS.

Now that the automobile art has so far advanced that there may be applied to it a paraphrase of the Kentucky gentleman's opinion regarding whisky, that "all cars are good but some are better than others," the expectant buyer looking for a car is more likely than ever before to make price the basis of comparison and a leading consideration in his decision.

It is no longer necessary to question whether a car will give service, but to seek the relationship between service and outlay. Another requirement in addition to the extent to which the car is to be used ought to be clearly in the mind of every economical buyer, before he makes his selection, namely: Whether he is going to demand high sustained speed over all kinds of roads, or whether, on the contrary, he is going to use his car at low speeds and to drive considerately over all rough places. If a man expects to "jam" his car, at speed, over all kinds of road conditions, the economical car for him is altogether another proposition than that adapted to the owner who is not only a moderate driver but a careful one.

The writer believes that the chief difference in the practical performance of the high priced and the low priced car lies in the ability of the former to serve at high speeds under arduous conditions, for long periods of time, with less breakage, less rapid depreciation, less need of adjustment and more comfort to its passengers than will the low priced car.

It is a salient fact, brought out year after year by the Glidden Tours, that very few cars, of whatever grade, are capable of being run at the maximum speeds at which their motors are well able to drive them without suffering breakages of their running gears or transmission parts. That is, the engines are more enduring than the rest of the cars they propel. But it is also a demonstrated fact that the high priced cars, on the average, approach more

nearly, as vehicles, to an endurance comparable with that of their motors than do low priced cars in general.

The lesson to be drawn from these facts seems quite obvious: If a car is required to be pushed to its limit of performance the major part of the time, a high grade vehicle will be most likely to give satisfaction. On the other hand, there is reason to believe that a low priced car, run, on the average, at only a fraction of its available speed and given some consideration at all the rough places, may give nearly if not quite as long and satisfactory service as the high priced vehicle used strenuously. It is safe to say that a good, low priced car will last as long, under conditions of easy driving, as the average owner will care to use the same car.

The above considerations are of course entirely apart from those relating to the differences of style, appointments and the quality of the finish found in the two classes of cars, but it should be remarked that the slow and careful driver has less need of the high priced car than the hard driver, because he requires less power, and the high priced car is in general the high powered car. Furthermore, as the slow speed driver operates his engine closely throttled most of the time, he will secure better fuel economy from the small engine, which is generally found on the low priced car, than from the large engine generally installed in a high priced vehicle.

A WORD OF ADVICE.

One closing suggestion to the prospective buyer. Do not try to get too large and too powerful a car for too little money. A small sum will buy a good low powered car, and a large sum of money will buy a fine high powered car of large capacity, but a small outlay will not yet suffice for the purchase of a big car which will be a profitable investment. There may be exceptions, but this statement is substantially true. This "don't" applies to all prospective buyers, but especially to the one who is a hard driver. The easy driver may get along with the cheap, big car, and be able to swing considerable style with only moderate current repairs, but the fast and careless driver will almost infallibly come to grief, for the big bore motor of the cheap car will be likely to pound the car as a whole to pieces, in a period of time much less than the normal life of an automobile.

According to a report from Milan, Italy, the Government has recently opened an automobile line from Courmayeur to the hospital on the Little St. Bernard, at an altitude of about 9,000 feet above the sea level.

Another attempt to reorganize the cab service of Vienna on a motor basis is to be made this fall, when 300 taxicabs are to be placed in service. A number of cabs for the training of drivers have already arrived. The date on which the service is to begin has not yet been announced.

# "Twenties" a Prominent 1910 Feature,

Recent years have witnessed a decided reduction in the size of motors of the four cylinder type in general use, the employment of cylinder bores of over 434 inches having become rather uncommon. Bores ranging from 4 to 41/2 inches have come to be much more generally employed than hitherto. The development of the six cylinder motor and its employment for high horse power is partly responsible for this, but the lack of sweet running qualities and the inability to operate for long periods without mechanical attention has been an important cause leading to loss of popularity upon the part of the very large bore four cylinder engine. Moreover, a certain portion of the public has come to a realizing sense that great power is not only not a necessity but is economically undesirable.

The season of 1909 has witnessed the sale of a very large number of cars known as "thirties," equipped with motors of about 4 inch bore, as well as a large number of cars with 4½ inch bore motors and a considerable representation of vehicles with 4½ inch bore engines. The 4 inch bore engine, numerically speaking, has been ex-

ceedingly prominent, and the "thirty" has been rather a feature of this season, as cars of this rating have generally been sold at popular prices.

That the extensive use of four cylinder motors of less than 4 inch bore is to be looked for is indicated by the recent appearance of several models of runabouts, roadsters and small four passenger touring cars, equipped with motors rated at 20 horse power or thereabouts, and of about 3¾ inch bore.

The four cylinder motor of about this bore has been prominent abroad for some time past, and it is reported to have proved itself very economical in operation. There is no doubt that, if well built, a four cylinder engine of this size is very quiet running and durable, and that it is ample in point of power for runabout and light four passenger service. Considering the reasonable prices at which cars of this kind bid fair to be sold, and the reasonable expense at which it should be possible to operate them, it may be expected that their advent may accomplish much in the direction of extending the use of the motor car in quarters where it has been little employed hitherto. It may be that the "twenty" will prove as much of a factor in the market within a short time as the "thirty" has during the present season.

Experience has shown that the automobile buying public demands a motor of at least four cylinders, even for very moderate horse powers, and it seems likely that the motor of about 3¾ inch bore, with its "hummingbird-like" performance and moderate fuel consumption, will appeal to a very large body of buyers of moderate tastes

# Preventives Against Steering Gear Accidents.

Accidents brought about by breakage or disconnection of the steering gear are relatively rare, but when they do occur they are generally of a very serious nature. An instance in point occurred in New Jersey last week when two persons were killed and several more injured as the result of accidental disconnection of the steering rod. It would seem that, especially in connection with fast cars or in mountainous districts, the fatal possibilities involved in failure of the steering mechanism really call for the provision of an emergency steering gear that can be used when the regular gear fails. Emergency brakes are fitted to practically all cars, yet under most circumstances a failure of the brakes is less fraught with danger to the occupants than failure of the steering ear. Of course, brakes become ineffective through wear of their frictional surfaces more frequently than steering gears, but this difference may be regarded as compensated for by the greater seriousness of steering gear failure.

Conscientious construction—that is, the use of the best materials, liberal dimensions of parts and the provision of reliable locking means to all joints—will do a great deal toward eliminating the risks; but the fact remains that the safety of the occupants depends upon the integrity of a single linkage of quite a number of parts, and either the breakage or disconnection of this linkage while the car is being driven at 30 miles per hour or more means almost certain death.

In all other cases where human life depends upon the failure of mechanism, as in elevators, for instance, suitable safety appliances are provided, and it would seem that something of this sort should be fitted to all high powered cars at least. The provision of an emergency steering gear would seem to be the most practical plan. As in the case of brakes, the two gears should be absolutely independent, so that no defect of one could possibly interfere with the other.

The provision of double tie rods, in front and back of the front axle, respectively, was advocated in these columns some years ago, and we believe that the idea has been applied in practice to a limited extent. An emergency steering gear would, besides, include an extra steering wheel and post, an extra reducing gear and an extra steering rod. The reducing gear would have to be of the reversible type (bevel or spur gear), as it would under normal conditions be operated backward by the driver. The emergency steering wheel could probably be located directly underneath the main steering wheel, concentric with it. Ordinarily it would be impossible to steer the car by the emergency steering gear, owing to the locking effect of the irreversible main steering gear. But if the main steering rod should break or come loose at either end, which would render the main steering gear ineffective, the car could be steered by the emergency gear.

There is naturally a good deal of disinclination to load down a car with extra mechanism that may possibly not once be used during its entire life, and the more inviting path to improvement is along the

line of rendering the joints in the steering linkage more secure. But it seems to be impossible to devise a mechanism that is absolutely infallible, especially when subjected to the abuse and neglect that are often the lot of an automobile, and it would certainly be a great comfort to many drivers to know that there is an emergency steering gear to fall back upon if the main gear fails for any reason.

### Distinctive Catalogues.

Every now and then some user of catalogues, who has been trying to reduce his collection to a semblance of order, breaks into print with a story of his troubles and forcible suggestions as to the advisability of standard sizes. Whether the people who issue catalogues ever read these tales of woe or not is a question; at least, the day of standard sizes seems to be as far off now as it was ten years ago. It would seem that the general idea is to have catalogues express individuality by their odd shapes rather than by any other peculiarity.

But while the advantages of standard sizes are manifold and cannot be too often emphasized, there are other points in the makeup of a catalogue which deserve more attention than they appear to receive. We refer particularly to catalogues of parts or accessories which are issued yearly and are sent out to the same buyers season after season. As was recently remarked in these columns, these catalogues merely serve to sell goods by, and no attempt should be made to have them resemble works of art.

The more clearly the goods are illustrated and described, the fewer the words in which the necessary facts regarding them are told, and the easier it is to find the article wanted the better does the catalogue serve its purpose. There remains the question of making the catalogue itself easy for the user to find, so that he shall give it preference over those of other makers when he is in a hurry to find something in this particular line. This can be done by making the catalogue distinctive in color and cover design.

If, when issuing the first catalogue for a line of goods likely to be manufactured for several seasons at least, some distinctive color scheme was thought out for its cover and adhered to as long as the goods were catalogued, this cover would gain in advertising value with every issue, for more and more people would recognize it. Quite a few companies have done this, but the maity have not, which makes the practice

all the more advantageous for those who have.

In most methods of filing catalogues they are placed so that they must be recognized by their backs, and unless some distinctive title is printed thereon, a recollection of the shape, size and color of the catalogue is all the searcher has to go by. When we consider this it seems strange that so few catalogues, even when thick enough, have anything printed on the back. The identifying title should always be there, and as a usual thing it should consist of something more than the firm name, for although the company may make only one kind of goods the searcher may not be familiar with the fact. So the title should, as a rule, include both the articles catalogued and the name of the manufacturer; in full if there is sufficient room for good sized type, or in some abbreviated form if not, but not so condensed as to fail of being perfectly plain to the average user. Both front and back covers should, of course, bear similar titles, together with the trademark, or some distinctive device.

We believe that if these few suggestions are followed the average catalogue will be much more valuable to its publisher, because it will be more serviceable to its user. A considerable experience in the use of catalogues has shown us that when they are needed most they are generally wanted in a hurry, so that the catalogue which can be found most readily and in which the article sought for is most conveniently displayed will be oftenest used.

While a distinctive and handy catalogue cannot take the place of good quality of material, workmanship and design in the goods catalogued, it may, we believe, go a long way toward making these necessary attributes of a good article more generally appreciated.

# Popularization of Electric Vehicle Lighting.

The employment of electric lights upon gasoline automobiles, which, up to within a very short time, has been so exceptional as to be hardly worthy of consideration as a practice of commercial importance, has extended in a remarkable manner within the last six months or so. Electric side and tail lamps are now no longer a rarity, and electric headlights are quite common. Indeed there are indications that electricity may soon become the accepted illuminant for motor cars, to the widespread if not general displacement of gas and oil.

The public, accustomed as it is to seeing electricity displace other illuminants in stationary lighting, seems very ready to welcome electricity in motor car lighting, and it is significant that several manufacturers of high grade cars are advertising electric side and tail lamp equipments as features of their 1910 models. This popularization of electric vehicle lamps is exerting a decided effect upon certain lines of electrical accessories used in the automobile industry.

The storage battery, the popularity of which in the ignition field has lately been seriously menaced by the general adoption of the high tension magneto, is finding a new and extensive field of application in the operation of high efficiency tungsten lamps.

The small direct current dynamo, driven from the engine, which never attained any very extensive application while the furnishing of the small amount of energy required in ignition was its only field of usefulness, has been brought into considerable prominence now that there has arisen a demand for considerable quantities of electrical energy to be used in lighting.

These small dynamos, arranged to be used in connection with storage batteries, have, in consequence, been rapidly improved of late, especially as to the automatic means provided for regulating the voltage, irrespective of engine speed, and as to the manner in which they are driven from the vehicle engine.

Even the magneto, of types other than the synchronous, has been affected by the demand for lighting energy, and these machines are now being constructed with a capacity in excess of that required for ignition purposes, which additional output may be used for lighting.

It would be strange indeed if the adoption of electric lighting should have its effect upon ignition practice, but it is not inconceivable that it may. It is not impossible that the general use of electric lights, with the large electrical generating and storage capacity which is involved, may adversely influence the popularity of the high tension magneto. The presence of a large storage battery capacity and a charging source installed upon a car for lighting service, from which abundant ignition curtent can unfailingly be drawn, may make the installation of a special synchronous magneto, for sparking only, appear superfluous.

Automatic car speed governor contests are now being held in Austria and Switzerland.

# Fuel Economy and Its Dependence on Engine Design.

The recent increase in the wholesale price of gasoline has still further added to the importance of so designing engines that they will operate with the least consumption of fuel. Economy in fuel consumption depends undoubtedly to a greater extent upon the carburetor than upon the engine, yet it is well known that quite a few points in engine design have a strong influence upon the amount of fuel used per brake horse power hour. The subject was forcibly brought to the attention of designers some years ago by a number of European contests in which the amount of fuel allowed the competing cars was limited; it also was brought home especially to American engineers through the fuel economy contests held in this country in recent years, though, owing to the fact that these latter contests were always announced only a short time in advance, and none of them partook of the nature of a national event, they naturally did not have any great effect upon design. These contests clearly showed, however, that air cooled motors are more economical of fuel than water cooled motors. This is, of course, due to the fact that the cylinder walls of air cooled motors are kept at a considerably higher average temperature than the cylinder walls of water cooled motors. It has been pretty definitely established that the horse power output of an engine decreases as the wall temperature increases above the minimum temperatures found in actual practice, but the fuel efficiency varies inversely as the output, and increases with the cylinder tem-

The various means available for increasing the fuel economy of engines may be summarized as follows: Maintenance of the cylinder walls at the highest possible temperature that will not interfere with proper lubrication; compression spaces of the least wall surface in proportion to cubical contents; dilution of the charge by an excess of air; increased expansion of the gases, and the use of long stroke motors.

### HIGH CYLINDER TEMPERATURE.

According to some experiments made in this country, the most efficient cylinder wall temperature is about 350°. The cylinder walls can only be maintained at this temperature if the air cooling system is adopted. The ordinary systems of water cooling do not permit of a higher temperature than 212° for the outer surface of the cylinder walls. Water cooling would admit of higher wall temperatures if the water system was closed and a certain steam pressure was maintained in it, but this involves so many objectionable features that it is not likely to be adopted. Where water cooling is adopted the aim then should be to keep the water in the jackets at as near the boiling point as possible. This is undoubtedly best accomplished with the thermo-siphon system of circulation, with which system the speed of circulation varies automatically in proportion to the temperature of the cylinder walls, so that the tendency is to keep this temperature uniform. The thermo-siphon system requires a somewhat larger radiator capacity, and is therefore not so well adapted to very powerful cars, which is probably the reason why it is not more extensively used at the present time. Aside from the advantage of automatic regulation of the circulation in accordance with the needs, the system has the advantage of simplicity, as compared with the pump circulating system.

The second method of increasing the fuel economy consists in using a compression space of such conformation that the wall surface is a minimum for the particular cubic volume required. It is at once obvious that all valve pockets and passages must be avoided, and that the valves must open directly in the cylinder. In the majority of motors in which the valves are thus located the cylinders have flat heads. as this permits of placing the valves with their stems vertical, thus simplifying the arrangement of the valve mechanism. The combustion chamber then has the form of a flat cylinder. It can easily be shown, however, that the same compression space can be obtained with less wall surface if the cylinder heads are doomed, and the compression space is made substantially hemispherical. This form of compression space has been used in this country for many years in the motors of the Welch cars, and it is also used in the Franklin motors, in which latter its use is facilitated by the concentric valves in the centre of the head. Where two valves have to be placed side by side in the head, the centre of the hemisphere is often flattened so as to permit of placing both of the valves vertically. In the Welch motors, however, the valves are placed at an angle of about 45 degrees each.

### DOMED CYLINDER HEADS.

A reduction in the surface area of the compression chamber is of the greatest importance, because the gases at the time of their inflammation attain a very high temperature, and a great deal of heat is lost through the compression chamber wall directly after ignition. From 30 to 40 per cent. of the total heat liberated by the combustion of the charge is lost through the walls. The loss of heat, of course, continues from the time the gases are ignited until the bulk of the spent gases has escaped through the exhaust valve, but the loss of heat is far more rapid during the first portion of the power stroke, when practically only the compression chamber wall is exposed to the action of the hot gases, than during the last portion of the stroke, when both the compression chamber wall and the cylinder wall are exposed to the heat of

the gases. The loss of heat through the walls is directly proportional to the area of the walls, and also directly proportional to the difference in temperature between the inner and outer surfaces of the walls. The temperature on the outside of the walls does not vary materially, but the temperature on the inside decreases very rapidly as the piston proceeds on its outward stroke and the charge expands, and an engine indicator diagram may be taken to roughly represent the variation of temperature inside the cylinder during the power stroke. This consideration shows that it is of the greatest importance to keep the wall surface down as low as possible during the first portion of the power stroke when the difference between the temperatures on the inner and outer surfaces of the compression chamber wall is very high.

#### LONG STROKES.

The above reasoning also shows why a long stroke motor is more economical of fuel than a short stroke motor. In order to generate a certain number of horse power it may be assumed that a certain piston displacement or cylinder volume is required. In order to obtain this cylinder volume we may either use a large bore and a short stroke, or a small bore and a long stroke. A little calculation will show that if a cylinder of given cubic contents is to have the least surface area, the diameter and length must be made equal. However, since the temperature in the cylinder during the latter portion of the power stroke is comparatively low, the amount of surface exposed to the action of the gases during this portion of the stroke is of little consequence. An inspection of an indicator diagram will show that the pressure and temperature inside the cylinder have fallen to a small fraction of the original values after one-eighth of the stroke has been completed, if the charge is properly dosed and ignition occurs at the proper moment. But even if all the conditions are not exactly right, the temperature has dropped to a low value after one-quarter the stroke has been completed, and the rest of the stroke may therefore be neglected in a consideration of the best proportion of bore to stroke.

Let us assume that we have a motor of equal bore and stroke, and that the compression space is cylindrical and of one-third the volume of the piston displacement—proportions which are commonly met with in actual practice. Then, at the beginning of the power stroke, the burning gases are contained in a flat cylindrical chamber of one-third the height as the diameter. It was shown above that the height and diameter of the cylinder should be equal in order to make the surface a minimum, and it will be seen that in our case the cylinder is

much too flat to meet this condition. Even at the completion of one-quarter of the stroke, when the temperature of the gases has dropped to a low value, the height of the cylinder containing the gases is still only seven-twelfths of the diameter.

Now, let us assume that we have a motor whose length of stroke is twice the bore. If the volume of the compression space is again equal to one-third the volume of the piston displacement, then the gases at the beginning of the power stroke are contained in a cylindrical chamber whose height is equal to two-thirds the diameter, and at the completion of one-quarter of the stroke of the piston the gases are contained in a cylinder whose height is seven-sixths the diameter of the bore. In this case the theoretical requirements are therefore practically met.

### INCREASED EXPANSION.

Another expedient for increasing the fuel economy of motors consists in increasing the expansion of the gases. The timing of valves has changed somewhat in recent years, and in consequence the gases are now expanded less, in most cases, than they formerly were. This is due to the early exhaust opening now found on most motors, the exhaust valves generally opening with about 45 degrees lead. It is also customary to close the exhaust valves only about 10 degrees after dead centre, and to open the inlet valves after the crank has passed through another 5 degrees. The inlet valves are closed from 15 to 20 degrees after dead centre so as to give the cylinder a chance to fill up at high piston speeds by reason of the kinetic energy of the gases. The useful expansion of the burning charge really ceases the moment the exhaust valve begins to open. If the valve is set to open with 45 degrees lead, this decreases the effective length of the expansion stroke about 12 per cent. The expansion can readily be increased by holding open the inlet valve until a portion of the compression stroke has been completed. The returning piston then forces some of the charge that has just been drawn into the cylinder, out again. In a four cylinder engine the charge thus forced out will enter the cylinder next in order in the cycle of operations, as each inlet valve is held open for more than a half revolution of the crank, and the periods of inlet valve opening therefore overlap. In this way, therefore, no charge is lost.

The inlet valve may be held open until the piston has completed one-quarter of the compression stroke, for instance, in which case only three-quarters of the normal full charge is retained in the cylinder and utilized. It is, of course, obvious that with this reduced charge the motor cannot develop quite as much power as with a full charge, but in addition to the advantage of increased expansion of the gases, whereby a greater proportion of the heat units liberated is practically utilized, there is the further advantage that the gases at the time of discharge from the cylinder are at lower pressure and temperature, and the problem of muffling the exhaust is consequently rendered easier. With the same compression pressure the average temperature in the cylinder is reduced by this arrangement, and it is therefore possible to slightly increase the compression pressure without encountering the danger of preignition.

#### DILUTION OF CHARGE.

Almost the same effect as obtained from increased expansion may be secured by diluting the charge with an excess of air. This subject has been thoroughly investigated in connection with the stationary gas engines. Where ordinary coal gas is used the theoretically perfect mixture contains about one volume of gas to six volumes of air. It has been found, however, in practice that when this proportion is used the charge burns with such rapidity that it is difficult to avoid preignition if a compression pressure of 70 to 75 pounds per square inch is exceeded. This difficulty may be overcome by diluting the charge with an excess of air, and compression pressures of as high as 140 to 150 pounds per square inch have been found practicable when the gas is mixed with air in the proportion of 1: 10 to 12. Operating with such dilute mixtures led to very important gains in respect to fuel economy. With the theoretically correct mixture and low compression pressure, the fuel consumption was about 28 cubic feet per horse power hour, while with the diluted mixture and a compression of about 140 pounds per square inch it was reduced to about 17 cubic feet per horse power hour. Seventeen cubic feet of coal gas contains approximately 2,100 calories. Automobile motors, on the average, consume 0.15 gallon of gasoline per horse power hour, containing 4,400 calories, which shows that there is still much chance for improvement in respect to increased fuel economy.

In one sense the dilution of the charge with an excess of air is simply another way of increasing the ratio of expansion of the gases. The excess air does not take part in the chemical action of the combustion, but it absorbs some of the heat developed during the combustion, which would otherwise be transferred to the cylinder walls. During the latter portion of the stroke it gives out some of this heat again. The presence of the excess air keeps down the temperature within the cylinders and retards the combustion, but it does not detrimentally influence the inflammability of the charge, as do burnt gases when present in too large a proportion.

The use of increased expansion in gasoline motors was recommended in an article by Harry E. Dey, which appeared in The Horseless Age a number of years ago. Mr. Dey recommended the use of automatic inlet valves with strong springs,

which would close the valve before the cylinder volume was completely filled. While this arrangement would serve the purpose, the method above described by closing the inlet valve only after the piston has completed a considerable portion of the compression stroke, would seem preferable because the amount of charge drawn in would be more accurately gauged, and would not depend upon such a variable factor as the tension of a valve spring.

It is quite possible to combine the two last described methods of increasing the fuel economy. viz., increase of expansion and charge dilution, and it is claimed that both were used by Bablot when he established the fuel economy record on a Berliet car in 1906, which created such a stir at the time. Bablot covered a distance of 100 kilometers at an average speed of 73 kilometres per hour on a fuel consumption of less than 9 litres of gasoline, and that with a four cylinder motor of 100 millimetres bore and 120 millimetres stroke, and a vehicle weighing in running order practically 1.400 kilograms.

The effect of these practices upon the cool running of motors was clearly evident during the Grand Prix race of the Automobile Club of France in 1907. The rules of this race stipulated that the competing vehicles must use not more than 30 litres of gasoline per 100 kilometres, and the various designers naturally employed every means known to them for keeping down the fuel consumption. In this race competed a number of vehicles with motors of 180 millimetres bore and 170 millimetres stroke (7.2x6.8 inches), which ran from the beginning to the end of the race without showing the least sign of overheating, in spite of the enormous cylinder dimensions. The following year the limitation on fuel consumption was removed, and instead the cylinder bore was limited to 155 millimetres. Fuel consumption did not count this time. and in order to make up for the reduction in the size of the cylinders, the manufacturers naturally used a charge which gave the most powerful explosion-in other words, a rich charge. The result was that the cars of some of the best known French makers were thrown out of the race by overheating of their engines.

# Grand Central Show Blanks Out.

Application blanks and space diagrams of the Tenth International Automobile Show. which opens in the Grand Central Palace. New York, on New Year's Eve, were sent out last week. All applications for space received up to Friday, October 1, 1909, will have equal consideration in the first allotment on Friday, October 8. The allotment of space to the members of the Motor and Accessory Manufacturers will be made by that association, as is the case with the members of the Importers' Automobile Salon. Members of the A. M. C. M. A. will have the first drawing of vehicle space other than that allotted to the members of the Importers' Automobile Salon.

# British Trials of Headlights.

The Local Government Board recently requested the Automobile Club of Great Britain and Ireland to investigate and report upon headlights used upon automobiles, and the club in consequence instructed its technical committee to make the necessary tests and prepare a report. The club had previously discovered that among the causes making automobiles unpopular with the general public was the use of dazzling headlights on cars while driven in populated centres, whereby other road users are blinded. The club held the opinion that this effect could be minimized and still enough illuminating effect obtained for all ordinary purposes, by properly controlling the cone of light. Some manufacturers had already given attention to this problem, and some lamps had been produced specially with this object in view. It was hoped that the test would bring out the points that should be considered in building a successful lamp of this type, and this, the club avers, has been accomplished.

### JUDGES' REPORT.

The principal lamp makers responded to the invitation extended to them to submit their productions for the tests, which were of a searching nature, and were so arranged as to demonstrate the optical properties of the lamps. Thanks to this co-operation, a thorough investigation was possible, and the tests proved that the dazzling effect of headlights could be minimized while at the same time sufficient light could be provided

The entry list was fully up to expectations. The firms engaged numbered twentyone, and the number of entries was fortyseven. Of these thirty-three were acetylene, twelve electric, one petroleum, and one gasoline oxygen.

The entrant was invited to set his lamp to the best advantage in every respect, both the height and the angle of elevation being left to his discretion, and note was made of the height of each lamp above the ground (Table II, colmun f).\*

The records referred to in the following paragraphs were taken in respect of each lamp, and Table II shows in summarized form the certificates of performance issued in each case to the entrant. The diagrams and the sketches and illustrations also appear upon the certificates.

The Range.—The distance at which the lamp gave a certain standard of illumination (one-tenth of a candle-foot) was measured down a line along which the entrant had centred the beam of the lamp.

The Horizontal Dispersion of Beam.—The width of the beam over which the illumination of the head lamp was not less than the standard was measured at half the above range, firstly, at 3 feet above the ground, and secondly, at the eye level, assumed for the purpose of this test to be 4 feet 6 inches from the ground. The width of the beam at 3 feet above the ground was taken, because a maximum of illumination obtained at this level is useful to the driver and does not cause trouble from glare.

The standard of light upon which the photometric measurements were based was the same for all the lamps, viz., one-tenth of a candle-foot; that is, the illumination received upon a surface I foot from a source of light measuring one-tenth of a candle power.

The judges adopted this standard as giving a range at which details could be distinguished, but it should be remembered that the useful range of the lamps, i. e., that at which objects can be seen, is often substantially greater than that given in column g of Table II. The full effective range depends upon the nature of the object, e. g., its size and color contrast.

The Dazzling Effect.—The distance in front of the lamp at which an observer

could distinguish an object placed 6 feet to the side of, and 6 feet beyond, the lamp was measured. The object chosen was such that it could be discerned on a starlit, moonless, clear night at a distance of 100 feet in the absence of any headlight.

Back Reflection.—The term back reflection is used to denote the stray light thrown out rearwardly. Such stray light interferes seriously with the vision of the driver, and thereby operates to diminish the effectiveness of the lamp.

Prior to the tests the naked candle power of the burners and bulbs was officially measured. These results and the corresponding consumption figures are shown in columns a and b of Table II.

For the sake of facilitating reference the acetylene and electric lamps have been arranged according to their candle power, and the details of one lamp, the gasoline-oxygen, which is a type of limelight, have been set out separately.

Design and General Construction.—The lamps remained in the possession of the club after the tests, in order that the design and general construction might be investigated; at the same time sketches were made of the optical arrangements of the lamps, and are shown in Appendix I.

Under the heading of simplicity of design and general construction, the judges attach importance to the following points: Weight for size; ease of cleaning; absence of liability to rattle; fewness of parts; quality of hinges, clasps, supporting sockets, etc., and general method of assembling the lamp. Many of the lamps examined showed that entrants had paid considerable attention to these points.

The measurement of the candle powers of the sources of light has brought out the fact that the generally accepted idea of the intense candle power of headlights is erroneous. The naked light of a head lamp such as is usually employed is from 15 to 25 candle power, and this light is collected and directed by lenses and mirrors. Thus Table II, column a, shows only two acetylene burners exceeded 30 candle power, while in the case of electric lamps the number was the same.

In the opinion of the judges, so long as the optical arrangements of the lamps are efficient, ample illumination is afforded by about 20 candle power, which can be obtained in the case of an acetylene lamp with a consumption of about .7 cubic foot of gas per hour (about 2.8 oz. of calcium carbide), and in the case of an electric lamp with a consumption of about 21 watts.

It is to be noted that the larger the mirror and the smaller the source of light, the easier it is to avoid undesired dispersion of the beam. Accordingly, when considering the advantage of a light weight lamp, the importance of the size of the mirror must not be overlooked. The weight of all lamps is given in Table II, column e. The lamps marked †† are self-contained, and were weighed with the generator empty.

For the purpose of the tests the relation

of both pressure and consumption of gas to candle power was investigated. Some examples of these tests are shown in Table I.

From these experiments it will be observed that the candle power of an acetylene burner varies but little between pressures of 3 inches and 6 inches of water, but the consumption rises to an important degree. In the opinion of the judges, lamps and burners as now constructed require no pressure higher than 4 inches, and the most economical pressure is 3 inches of water. Increasing the size of the burner has small effect upon the range, unless the optical system is altered proportionately. Increasing the size of the burner tends to increase the width of beam, and in some cases the glare.

The effect of variations of voltage on electric lamps depends upon the substance of which the filament is made. The increase of light resulting from an increase of voltage in the case of metallic and carbon filaments is shown in the following table. For example, a 5 per cent. increase of voltage gives approximately a 31 per cent.

increase of light in the case of a carbon filament lamp, and 23 per cent. in the case of one with a metallic filament.

No. 16.—Fitted with front lens cut horizontally into a large number of sections, the adjoining faces of which are frosted.

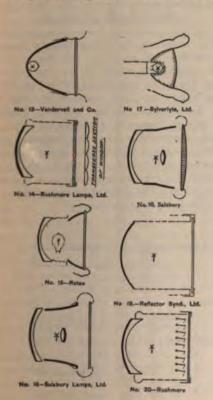

†† These lamps are self-contained; the weight therefore includes that of the generator.

somewhat overrun, and if this practice became general it would lead to objectionable results, on account of the blackening of the bulbs and premature breaking of filaments. The candle power of the electric lamps shown in Table II, column a, corresponds to the voltage at which the lamps were actually run during the tests.

A series of experiments were carried out to ascertain the effect on dazzle of varying the vertical angle of projection of the beam and the height of the lamp itself from the ground.

The figures given in the following Table IV. represent in general the results of the

tests made. The figures in feet in the different columns are the distances of the observer from the lamp at which he was no longer dazzled—a similar set of observations to those shown in Table II, column k.

Table IV.—Effect of Height and Angle of Elevation Upon Dazzle.

	Height of Lamp from Ground.								
Angle of Elevation.	2 Ft. Ft.	3 Ft. Ft.	4 Ft. Ft.	5 Ft. Ft.	7 Ft. 6 In. Ft.				
20 deg. up

the same of the same of			-						

This table shows that the least dazzle is obtained either when the lamp is very low down (2 feet from the ground), or when it is fixed above the canopy level (7 feet 6 inches above the ground). When the lamp is at, or about, a height of 3 feet from the ground, a downward tilt increases the dazzling effect. The judges are of opinion that this is due in a measure to reflection from the surface of the road, although this was not as light in color as is often the case.

When the lamp was tested below the level of 3 feet from the ground maximum dazzle was obtained with an upward tilt. Nevertheless, the effect on dazzle of tilting the lamp within reasonable limits is unimportant.

Undue tilt of the lamp causes considerable difference in the illuminating power, whereas height has an appreciable effect in diminishing the dazzle. The best position would appear to be at 2 feet.

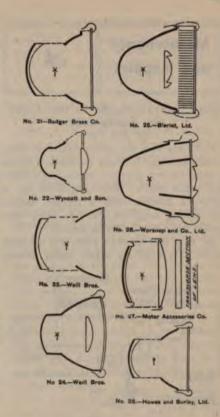

As regards illumination the horizontal is the best position from the driver's point of view, except at a height of 7 feet 6 inches, when a slight downward tilt is desirable.

The automatic anti-dazzling devices other than specially arranged mirrors or lenses appeared in every case to diminish the range, but in one case this effect was only slight.

Three lamps were provided with gold reflectors, a development which is expected in consequence of the color to prove of advantage in time of fog. It was not possible to adjudicate, in this respect, upon these or other lamps with similar claims, owing to the absence of fog during the test.

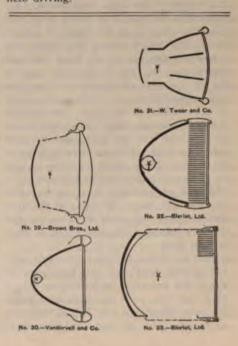

Appliances can be added to almost any type of head lamp whereby the light may be reduced; for example, with electric lamps by a switch diminishing the voltage or inserting resistance, and with acetylene lamps by partly or wholly obscuring the light by means of hand-actuated shutters or screens. The advantage of such a hand-actuated device is that on entering a town the intensity of the light from the head lamp can at once be moderated.

The lamps have been tested singly, but in many, if not in most cases, users employ a pair of lamps. It should be noted that a wider beam is required from a lamp which is to be used singly.

# Noiseless Universal Joint for Magneto Drive.

A simple method of flexibility connecting a magneto to its driving shaft that is used on one of the latest English trucks, and that would seem to be particularly applicable where a magneto is fitted to an old car, consists in securing fork shaped castings to the ends of the magneto shaft and the driving shaft and bolting the prongs of the two forks to a heavy leather disc, at right angles to each other. This affords a perfectly universal drive, and one having the advantage of absolute silence over the ordinary universal couplings used for magneto driving.

# Maintenance and Repairs

# Some Improvements to the Lighting Equipment. By JAY TEEL.

For some time my father has been using a runabout for business purposes. It has a one cylinder gasoline engine with make and break spark. For ignition it has a governed dynamo with a storage battery for starting purposes, the two being con-

At first the car had only two oil side lamps, and when my father began driving

trolled by a double throw switch.

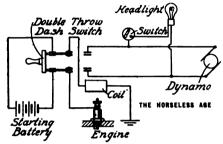

DIAGRAM OF WIRING.

much at night he found that he needed a headlight, as the roads of this vicinity are very rough and rocky. He purchased a 7 inch, mirror lens headlight and had a piece of metal rod bent into a fork to fit it. The next thing was to fit it to the car. As the dash of this car is really a large door, hinged at the bottom, the lamp could not be put there. As there is a metal rail just above the dash, and the bonnet of this car slants downward along its entire length, the radiator being carried below the frame, it could not be conveniently placed on top of that. It was finally decided to place the lamp in front of the bonnet, fastened to the bottom of the angle iron frame. My father had two pieces of heavy strap iron joined together so as to form a T section piece. The lower part of the T does not extend all the way to the front end, and toward the rear has a strip cut away at the top just wide enough for the iron plate to be slipped through. There are two pairs of holes drilled in the plate. Through the forward pair go two lag screws which are screwed into the body, and the rear pair hold bolts which go through holes in the frame. These cause the plate to hold the T section piece clamped firmly in place. The front end of the T piece was forged to conform with the cross section of the fork. Another piece was made to fit on top and the fork was held clamped firmly in place by four bolts.

First my father bought a generator with a "capillary feed" for the headlight. It was a \$16 generator, but he obtained it for a good deal less, as it had been used some. We soon discovered why it had been sold so cheaply. At the first trial it worked

finely. There was a large white flame at the burner which, reflected by the mirror, gave a broad white beam of light, which sl.owed all the rocks and ruts, and flooded the road for some distance ahead with its light. After the auto had been put back into its house, however, and the water turned off from the generator, the lamp did not go out.

"It will be all right," I said. "Just let it burn a few moments until the gas already made is burned, and then it will go out." We left it. About an hour and a half later my father went back and found it burning its brightest. He then unhitched the tubing from the generator and emptied out the water. When we investigated we found that the carbide chamber was a sort of horizontal pipe. It was divided lengthwise into two parts. The upper part extended more than half way to the bottom. The lower part extended beyond and outside of the upper part and was clamped to it when the water was turned off. Against the outside of the pipe thus formed flowed the water, and turning the latter on was merely loosening the clamping device. Particles of carbide lodged in the cracks between the two parts and thus prevented the flow of water from being stopped.

My father next tried a generator in which the water is above the carbide. When the key is turned the water drips down into it. This worked a little better, but it was affected somewhat by the vibration of the car and it was found expedient not to put the water in until the lamp was to be used and to empty it out again when it was put out.

Probably neither of these would be called first class generators, but my father neither wished to pay a high price for such an article nor put up with such poor ones as we had. He had the output of the dynamo measured and found out how much current was not needed for ignition purposes. He had an electric lamp socket put in place of the gas burner in the headlight. He fitted it with a tungsten lamp, wired as shown in the sketch of the dynamo wiring. He has used this ever since, and there has never been the least bit of trouble from it. The light is always ready at a turn of the switch key, and the lamp gives plenty of light. I do not think the total outlay in this case amounted to two dollars. It was merely the best and most convenient solution of the problem. Gas was not discarded for electricity as a whim or experiment. It was only a matter of which was the least troublesome and expensive.

#### Valve Treatment.

Many a difficult case of missing at very low speeds has been accounted for by the valve stem being loose fit in the valve guide. Most valve guides are of cast iron. If, however, it is necessary to bush them an excellent bush may be made out of mild steel, provided it is carbonized, i. e., soaked in carbonizing material such as bone, burnt leather, or scintilla, for an hour or more at a bright yellow heat closed up in a pot. Thus treated, mild steel will replace (more advantageously) cast iron anywhere, and has remarkable anti-friction properties. This same treatment can be applied with great success to all valves. Care is necessary not to attempt this to nickel steel valves, or any but mild steel valves of .18 per cent. carbon content or less. They then have the virtue of not pitting, and the stems practically never wear at all. The Talbot Company's valves were always case hardened all over, and corrected by grinding after hardening, and it is well known that up to the end of 1908 that company had never changed a valve whatsoever.

Speaking of valves, another mysterious cause of apparent misfiring hard to locate was when the valve stem was too good a fit in the valve guide, and occasionally stuck up instead of coming down.

Another discrepancy has been found in many repair shops. The part of the cam which should have been truly circular was not so, and a bump or prominence left on the back sometimes lifted the valve slightly off its seat, and often caused the carburetor to ignite.—The Autocar.

# New Mode of Travel.

A new method of travel was tried out this month by the United States Senate Committee on Irrigation and Reclamation of Arid Lands, which left St. Paul, Minn. on August 12, and reached Portland. Ore on August 22. The committee traveled by a special train on the Northern Pacific. The train comprised a number of automobile combination cars, two baggage cars and a number of automobile cars for transporting automobiles, by which the party made side trips of inspection at a number of points. The automobile cars were veritable garages on wheels.

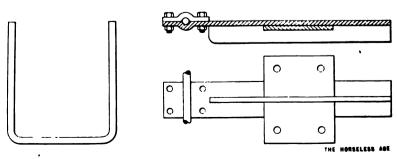

DIAGRAM OF HEADLIGHT BRACKET.

# **NEW VEHICLES AND PARTS**

# The Flanders Twenty.

This new car is being manufactured in the Detroit factory recently occupied by the De Luxe Company, but now owned by the E-M-F Company. It is being made in a separate factory by a new organization, but under the experienced control of Mr. Flanders, of the E-M-F Company, and his associated manufacturing experts. The cars will be marketed by the Studebaker Company.

The car is designed especially for manufacture in very large quantities, an output of 25,000 being promised for the first year. It presents, therefore, many features which may appear radical at first sight, but closer inspection will show that they are logical developments which are to be expected as the number of cars to be manufactured in a season increases.

#### THE SAVING IN ASSEMBLING.

The feature which most strongly attracts attention at the outset in inspecting this car is the manifold uses of the tubular underframe. Tubular underframes are not new: they have been used both in this country and abroad, but they have usually carried only the motor and change gear. In this car the two parallel tubes carry nearly everything, viz., motor, radiator, dash, steering gear, pump, magneto, coil. The change gear is mounted on the rear axle. Thus the entire power plant is assembled on the bench and put in place in the frame as a unit. If the cars are being used for commercial purposes this unit may be removed for repairs or adjustments and replaced by a spare unit. The same thing may be done in any city where a considerable number of these cars are used for pleasure purposes. In this way, barring some accident which would completely wreck the car, a machine can be kept in service all the time.

### THE MOTOR.

The bore is 35% inches and the stroke 334 inches. All four cylinders are cast together. The valves are in pockets all on one side, operated from a single cam shaft by straight tappets. The valve chambers are closed by screw plugs. The top of the water jacket is cast open, and is closed by a pressed steel cover, retained by four studs, one at the centre of each cylinder head, which draw it down tightly on its gasket. Its edges are flanged downward to retain the gasket. At its front end a short pipe is pressed out at an angle of about 30 degrees with the horizontal, to take the hose connection to the radiator.

The valves have beveled seats, are 11% inches in clear diameter, and slide in guides pressed in from the outside. The springs are cylindrical and are retained by a pressed steel cupped washer which is fastened by a horseshoe shaped washer that fits a groove turned in the valve stem. They are operated by tappets of nearly rectangular section, which slide in die cast guides that are fitted into bosses cast on the bottom

flange of the cylinder castings. Their section prevents them from turning, which allows of the ends being rounded like a roller. A hard fibre plug is placed in the upper end. These tappets are made very hard, with the length to gauge. Valve seats are machined to a uniform height from the cylinder base. The valves are all made exactly the same length, and the cams are ground. In this way uniform timing is secured without adjustment.

The exhaust manifold is cast with the cylinders, and its side is provided with cooling ribs. The outlet to the muffler is through a flanged connection at the rear. The two openings to the inlet valves are underneath the valve pockets. A Y pipe leads to the carburetor.

The crank case is of the barrel type, with open ends. It has four holes in the top where the connecting rods pass through, and four holes in the bottom for adjusting the connecting rod bearings. These latter holes are closed by plates, held by studs and yokes. The crank shaft is of the two bearing type, drop forged, with pins 118 inches in diameter, and 134 and 134 inch front and rear bearings, respectively. The flywheel is pressed on a taper, secured by a Woodruff key and held by two lock nuts with a slotted washer between them.

The crank shaft bushings are die cast of special bearing metal. On the first cars the crank case will probably be made from a special gray iron, but dies are being developed to make them from drawn steel.

The crank case ends, which carry the crank shaft bushings, are cast with arms whose ends are bored to take the underframe tubes. These arms are slotted and fitted with clamp bolts. The support for the bearing is fastened to the crank case end plate by ribs so that the splash can' fall into large pockets on top and run back into the crank case after lubricating the bearings. All parts of the motor are lubricated by splash, which is supplied from two crank case compartments. The oil level is maintained by vacuum feed from a pressed steel tank at the side, supported from one of the underframe tubes. This is the system used on the E-M-F cars during the past year.

The cam shaft has three bearings, and integral cams. All its working parts are ground. The cam shaft and magneto driving gears are of the single spiral type. They are enclosed in a pressed steel case, but this case is simply a housing and does not support the gears in any way. The gears are rigidly supported by the crank case, and the centre distances are kept very accurate, so they may run as quietly as possible. A projection on the front part of the gear case carries the starting crank, which is pulled out of engagement by an outside spring.

The pump is of the centrifugal type; it is mounted on one of the underframe tubes and is driven by the magneto gear. It is at the centre of the motor, and delivers water just below the two middle exhaust

valves. The radiator consists of two tanks connected by quarter inch vertical tubes surrounded by continuous horizontal fins. It is made up rough, and is surrounded by a finished cover whose shape closely resembles the well known Studebaker design. This allows of the radiator being readily repaired. It is carried on two brackets, which are pinned and clamped to the forward ends of the underframe tubes. The fan is driven from the cam shaft by a flat belt.

A Splitdorf magneto supported on one of these tubes supplies current for regular running. Starting current is furnished by dry cells. The coil is in a cylindrical hard rubber case secured to the under side of a tube. The cut-out switch is mounted on the dash, and the only wire leading away from the motor is the low tension wire to this switch. This dash, by the way, is made from pressed steel, shaped so as to resemble a flat wooden dash about fiveeighths of an inch thick. It has the support for the rear end of the hood pressed integral with it. The clamping bolts for the year legs of the motor extend upward and support the dash.

The clutch is of the leather faced reversed cone type. Both male and female cones are made from pressed steel. The spring is a large diameter conical one. A ball thrust bearing takes the spring pressure when the clutch is disengaged. The cone runs on a die cast white metal bushing.

Back of the clutch is a single universal joint consisting of two forks with radial pins connected by a ring split in the plane of rotation. The squared hubs of the joint forks are free to slide a little fore and aft so that the joint may centre itself with the surrounding globe.

This globe joint, which is secured to the front of the tapered tube which surrounds the propeller shaft, is of a new type. It consists of a pressed steel piece, considerably less than hemispherical, which contacts with the outside of a hemispherical projection pressed in the cross member of the frame. Through slots in this cross member globe it is bolted to a zone ring which takes the thrust when the brakes are applied or the reverse is engaged. The front of the joint is enclosed by a cover of thin pressed steel.

The propeller shaft and differential casing are mounted on cup and cone ball bearings. Driving bevels and change gears are carried in a malleable iron case open at the sides. This forms the centre of the rear axle housing, as in the E-M-F Thirty. The gears are 6-8 pitch. The fixed gears are keyed and pinned, and the sliding gears are mounted on a square shaft. Cup and cone bearings are used throughout, except back of the pinion shaft, where an annular ball bearing is used, since the thrust must be taken in both directions.

The direct drive clutch is of the internal-external gear type. The lay shaft is above and the shifting rod below. Two speeds and a reverse are obtained with a single shifting rod.

The differential is of the bevel type with two pinions. Its case is of pressed steel, and the driving gear is bolted between the halves. The case is mounted in cup and cone ball bearings carried in vertically split supports, which are cast with the gear case. The sides of the case for the sliding gear have large hand holes, which are closed by pressed steel covers. The remainder of the rear axle housing is formed from two conical pressed steel pieces, which close the sides of the driving gear case, and two tapered tubes which are brazed into the cones. and which form covers for the axle shafts and supports for the bearings and springs. This construction gives a light axle of large diameter which does not need a truss rod.

The axle shafts are secured in the differential gears by a tapered fit, key and lock nut, and are fastened in the wheels in a similar manner. Hyatt bearings are used at the wheels, 4 inches long, with one-half inch diameter rollers.

The front axle is a drop forging made in a single piece. The axle bends down outside the spring seats and is also curved downward between the seats. The seats are separate, and the springs are secured by a single wide clip, which passes through the centre of the axle, surrounded by a spacer between the flanges of the channel.

The knuckles are forged and are bushed with bronze. The knuckle pins are hardened and have nuts at the bottom. The wheels are ball bearing and have 11/2 inch spokes.

The front springs are semi-elliptic and the rear springs are scroll head full elliptic, shackled at both ends. They are 13/4 inches wide. The rear spring seats are of pressed steel and turn between collars fast on the axle tube. The springs turn on pins secured to the frame, so by removing them from these pins and taking out the four bolts in the globe joint the axle can be removed from the car.

The frame is of pressed steel, neither dropped nor narrowed. The power unit is supported on a cross member in front and by two saddles under the rear motor legs, making a three point support.

Both sets of brakes expand inside the rear wheel drums. They are 9½x1 inch. cam expanded, cast iron shoes against pressed steel drums. Neither set is equalized. One set is operated by the pedal which throws out the clutch and the other by a hand lever. The levers and pedal are made from channel section pressed steel with forged ends.

Steering is by a worm and sector gear, which is fastened to the tubular underframe and to the pressed steel dash. It is cross connected to the left knuckle. Spark and throttle are controlled by levers under the wheel.

The body is made from pressed steel. It is of the same type as the Studebaker "Suburban." The rear seats are removable, and when they are off there is a large carrying space at the rear.

Each side piece below the seats is pressed from a sheet of steel, and is given a paneled effect by half oval ribs raised by pressing. The rear end is made in a similar manner. The sides and rear are fastened together by corner moldings and screws. The cross members, also of pressed steel, are fastened in by moldings and screws. The seats are of pressed steel bolted to the under body. Upholstering is done over a pressed steel frame, which fits down outside the top of the seats a little way, making a neat job. The flooring and sills are of wood, assembled and slipped inside the side sheets.

Body, frame, axles, and, indeed, all parts but the wheels, are finished in baked enamel. The wheel base is 100 inches, and the tread is standard. The wheels are 32 inch, with 3 inch tires.

With its readily removable parts, body with room for baggage, and its durable baked enamel finish, the new car promises to be suitable for many business purposes as well as for pleasure uses.

### Allen-Kingston Gunboat Body.

A new light weight four passenger aluminum body has been brought out by the Allen-Kingston Motor Car Company, of New York. It is called the "Gunboat" body, and is of the type first introduced by the Daimler Motor Company during the 1908 Prince Henry Tour. The body is very low, as the frame is dropped in front of the rear axle, and the seats are also low. A large, flaring hood extends back from the dash, almost hiding the low raked steering wheel from the front. The sides of the body form continuations of this hood, and the outline is quite smooth to the bulging stern back of the rear seat. Access to the front seats is by a door at the left, and the tonneau is entered by a door at the right. There is a large carrying space in the stern which can be reached by swinging up the upholstery of the rear seat, after removing the cushion. This body is claimed to greatly reduce the eddy currents at the back of the

car, owing to the smooth sides and projecting back, so that the rear passengers are less troubled with dust than in the regular bodies.

# An Ampere Hour Meter for Electric Vehicles.

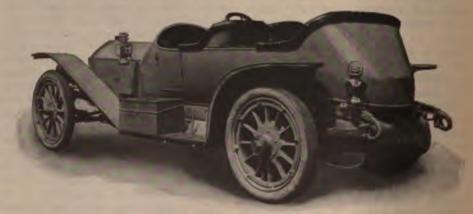

In the operation of an electric vehicle it is extremely desirable to know at all times how far the discharge has progressed, and consequently how much available energy still remains in the battery. An indication of the mileage which has been covered, up to a certain time, upon a particular charge, gives but a very crude idea of the actual draft which has been made upon the battery, unless

AMPERE HOUR METER.

the same roads, always in the same condition, are always traversed. When strange roads are traveled, with widely varying grades and surfaces and under diverse weather conditions, the mileage which has been covered is nearly worthless as an index of the remaining mileage capacity of the charge, and the operator is likely to be deceived into going so far from a charging station that, when exhaustion of the battery is indicated by a rapid fall in voltage, it may be difficult or impossible to reach a source of electrical supply.

In order to afford a continuous indication of the total of electrical energy discharged from a vehicle battery in operation, and thus to allow of an estimate being made of the energy remaining to be utilized, the Sangamo Electric Company, of Springfield, Ill., have brought

ALLEN-KINGSTON "GUNBOAT" CAR.

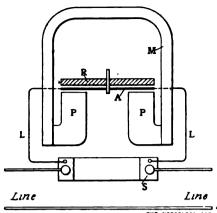

DIAGRAM OF SANGAMO D. C. AMPERE HOUR METER.

A. copper disc armature immersed in mercury; its shaft drives the recording train; L.L., leads from shunt S to chamber in which A is enclosed, carrying a certain portion of the load current to and from A. M, powerful permanent magnet, producing field which acts on curent through A to cause rotation. P.P., soft iron pole pieces to which M is bolted. R, soft steel plate above A, in the mercury chamber, acting as a return path for magnetic lines. S, shunt carrying greater part of load current; used in all sizes above 10 amperes.

out a special type of integrating ampere hour meter, intended for installation upon electric vehicles of all kinds. This instrument may be mounted upon the dash and affords a continuous reading, which is equivalent to the product of the average current in amperes which has been drawn from the battery up to the instant in question, and the time in hours during which this current has flowed.

The device is essentially a motor meter, the same in principle as the house meters on electric light circuits; but indicates in ampere hours instead of in watt hours. The moving element is a pivoted disc-like structure, through which the battery current passes diametrically from fixed, unspillable mercury contacts. Stationary permanent magnets, arranged in close proximity to this disc, react in such a manner upon the current flowing in the disc as to produce motion, and an aluminum dampening disc, turning between permanent magnets of its own and carried upon the jeweled shaft which supports the motor disc, reduces the rate of motion to proportionately with the current to be measured. An integrating train of clockwork, moved by the disc shaft, actuates a pointer which sweeps over a scale graduated to ampere hours.

The moving elements are buoyed up by the mercury, which is enclosed in a tight compartment for contact making purposes, and relieves the jewel bearing of most of the weight of the mechanism. The mercury also acts to dampen the effect of shocks, and it is claimed that these instruments may be used for long periods upon vehicles subjected to severe vibration without detriment.

By the employment of various ratios in the gearing and other modifications, these instruments may be given any desired range as to maximum current and total indication, and thus may be made suitable for installation on electric vehicles of all sizes. Instead of indicating upon several small dials, in units, tens, hundreds and so forth, this instrument is fitted with a single dial reading from zero up to a number of ampere hours somewhat in excess of the capacity of the battery with which it is to be used. It is so connected into the vehicle circuits that all current entering the battery for charging purposes and all that leaving it, as discharge, passes through its motor disc. When charging current is passing through it the indicating hand moves in one direction, and when the battery is discharging the hand moves in the opposite direction. If, then, the pointer is placed at zero and 150 ampere hours of charging current, for instance, is passed through it, the hand will stand at 150, and if the battery were perfectly efficient 150 ampere hours could be drawn from it. During the discharge the hand would gradually recede toward zero, and its indication, at any instant, would register the remaining ampere hour value of the charge. Since, in practice, the ampere hour efficiency of a battery is always less than unity-80 per cent. is a fair figure—it is usual, after the charge is completed, to set back the hand toward zero an amount equal to the expected loss in ampere hours. For instance, if 150 ampere hours are recorded upon the charge, the hand may be set back, manually, to 120 ampere hours, and the indications of the hand, during discharge, will correspond, quite closely, to the remaining ampere hours in the bat-

The known efficiency of the battery will determine the amount of this required allowance, and at the same time any change in efficiency will at once become evident by a failure to realize in service the expected ampere hour capacity.

A substantial cover protects the instrument, and the device for resetting the pointer is operable only by the use of a special key which is carried by the owner. If the instrument be left reading zero at the time a charge is ordered the indication of the meter, when the owner takes the car as charged, is pretty good evidence that that number of ampere hours has been put into the battery.

It then only remains for the owner to free the pointer setting device by means of his key, and to deduct from the indication of the instrument the number of ampere hours which experience has shown the battery in its then condition to lose per charge, when its succeeding indications will very closely represent the remaining ampere hour capacity available.

These instruments are fitted with a contact device, operated by the pointer when it reaches a predetermined point on

the scale representing the usual ampere hours of charge. This contact device, when used in connection with a relay, a source of current and an electrically tripped switch in the charging circuit, provides for the automatic termination of the charge at the desired stage and frees the owner from the necessity of watching his battery during the charging operation. The results obtainable by this method should be much more exact than by the use of a time switch, and probably more certain than by relying upon the rupture of the arc in the mercury rectifier, due to the rising of the voltage of the battery.

Overcharges and overdischarges are at once indicated by the pointer passing above the predetermined point of full charge on the one hand and by the pointer receding past zero on the other.

The B. & S. Igniter.

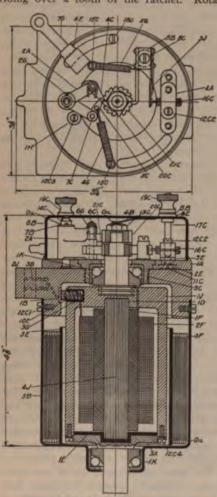

The Briggs & Stratton Company, Milwaukee, Wis., are manufacturing an ignition equipment designed along novel lines. The complete outfit, with the exception of the battery, is mounted directly on the engine. The igniter forms a cylindrical block 31/4 inches in diameter by 5 inches high and comprises a non-vibrating spark coil with condenser, a mechanical circuit breaker, a high tension distributor and means for timing the spark. Since a mechanical circuit breaker is used, only one spark is produced per ignition, and one of the chief claims for the igniter is its high current economy, it being stated that a four cylinder engine can be sparked with this outfit for 2,500 miles on one charge of a six volt, 60 ampere hour storage battery. The igniter is intended to be fixed to the engine frame and to be driven by means of the vertical shaft usually provided for driving the timer.

The rotating part or rotor consists of a vulcanized hard rubber case with a bronze spindle at each end. The upper spindle is molded into the rubber, while the lower one is secured to it by screws. The high tension distributor brush is located near the upper end of the rotor and is directly connected to the high tension end of the seondary winding inside the rotor case. One end of the primary winding is connected with the upper spindle and the other with the lower spindle. The rotor carries both the primary and secondary coil windings and the soft iron wire core, and is mounted on ball bearings. Both windings of the coil consist of enameled wire, which makes the coil very compact, and at the same time insures very effective insulation. The enamel insulation will also resist heat better than the regular silk or cotton insulated magnet wire. After the rotor is assembled it is filled with a special hard wax to hold the different parts of the coil in place.

The igniter comprises an outer containing case consisting of a drawn aluminum shell. The space between the rotor and the walls of the aluminum shell is taken up by the con-

denser. The latter is insulated with a special grade of paper imported from France, and is so designed as to eliminate eddy current effects within itself. The high tension distributor block consists of molded hard rubber and has the metal parts cast in. The sides and face of the block are ground and polished.

The most interesting part of the igniter is undoubtedly the contact breaker, which involves a new mechanical movement and is claimed to produce a contact of absolutely uniform time regardless of the speed of the motor. Referring to the plan view of the circuit breaker, the four point cam 20C is keyed to the shaft of the rotor and rotates with it at cam shaft speed. The dog 4C is caught by the cam 20C in its path of rotation and advanced, carrying with it the bell crank 2A and bell crank 5C until the hook 5C has advanced one tooth on the periphery of the ratchet 21C. At this point the dog passes out of the path of the cam and the bell crank carrying the hook and dog is returned to normal position against fibre stop 1H by spring 4G. As the ratchet is free to turn on the shaft, this return of the bell crank will rotate the ratchet onetwelfth of a complete turn, as it has twelve teeth. At each advance of the ratchet the contact points on screw 16C and spring 3J are instantly brought together and separated by the finger of the contact maker riding over a tooth of the ratchet. Rota-

B. & S. IGNITER

tion of the shaft backward will produce no spark, as the cam will not engage the dog on a backward movement. All parts of the contact maker subject to sliding contact are milled from tool steel, hardened and tempered after being polished. Large iridioplatinum contact points are used. All springs used on the contact maker are wound from German piano wire.

In order to advance or retard the spark the cover plate is rotated between stops on the distributor block. The distributor block and outer case are not shifted, and the case may be rigidly secured to the engine base, thus eliminating the wobble common with timers. The secondary wires are not moved when the spark time is advanced or retarded, hence they can be securely fastened in place. The high tension terminals are provided with a retaining device which makes it impossible for them to shake loose.

# Stewart Ball Bearing Swivel Joint.

A patented and exclusive feature of the 1910 Stewart Multipolar Speedometer will be a ball bearing swivel joint which elimi-

STEWART SWIVEL TOINT.

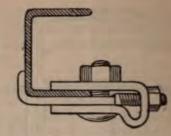

nates the bends in the shaft, permitting the shaft to be carried back along the frame of the car directly to the speedometer.

# Mesinger Double Check Spring.

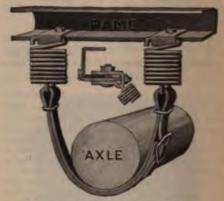

In addition to their single rebound check spring the H. & F. Mesinger Manufacturing Company, 1801-1803 First avenue, New York, are now offering a double check spring which is designed for cars that have full elliptic springs. The single spring cannot be attached to such cars because spring clips, bumpers or brake parts are in the way. The firm says that this spring can be put on any kind of car. They have also made an improvement in the clamp which fastens the spring to the frame. When attaching, the small nut is drawn tight, so that the bolt is pressed tightly against the frame, and then the large nut is tightened.

# Badger Motor Car Company to

Build Five Hundred Cars. The output for 1910 of the Badger Motor Car Company, of Columbus, Wis., will approximate 500 cars, in three models, all on the same chassis, as follows: Four passenger toy tonneau, two pasenger roadster and five pasenger touring car. The price is \$1,500. A four cylinder, 4x4 inch Northway motor, manufactured in Detroit, is used. The motor has a self contained oiling system and a thermo-siphon cooling system. Motor, clutch and transmission are assembled as a unit power plant. The transmission is of the selective type, giving three speeds forward and a reverse, and is

SPRING HOLDER

MESINGER DOUBLE SPRING CHECK.

equipped with F. & S. ball bearings and Brown & Sharpe gears. Many of the parts are designed by E. W. Arbogast, general manager and a director of the company, and will be produced in the Columbus factory. The company owns 22 acres on the main line of the Milwaukee road from Chicago to the Twin Cities, and a building, 50x150 feet, one story high, is now being erected. A. M. Bellack is president, Christian Kurth vice president, G. C. Holtz secretary, J. R. Wheeler treasurer, with William C. Leitsch an additional director. Webb Jay & Co. have been appointed Chicago agents for the Badger cars.

# Additions to Indianapolis Factories.

The Premier Motor Manufacturing Company, Indianapolis, Ind., has secured a building permit for the erection of a new factory building at Shelby and Georgia streets. It will be a two story brick structure and cost approximately \$15,000, according to the estimates.

The National Motor Vehicle Company, Indianapolis, Ind., will shortly let the contract for a \$25,000 addition to their factory at Twenty-second street and the L. E. & W. Railroad. The floor and roof of the building will be supported by a truss construction which does away with interior pillars. The building will be 154x200 feet and partly two stories high.

# Model Automobile Company Now Great Western Automobile

Company.
As an indication of their intention to broaden and extend their business the Model Automobile Company, of Peru, Ind., have changed their name to the Great Western Automobile Company. No change of membership or management is contemplated.

# COMMUNICATIONS

# Feeding Gasoline from Gravity Tanks on Steep Hills.

Editor Horseless Age:

I note the letter of J. S. Corbin in one of your recent issues, and wish to go him one better. Take an angle brass check valve with a brass ball and solder it tightly to the tank, run a one piece one-quarter inch copper tube to the dash, using unions with ground joints. To the dash fit a 1½x1 inch Lunkenheimer brass air pump. Then you have a fine equipment at small cost—one that is always ready for use, and that is very easily worked, too. There are no rubber parts to cut out, and the arrangement will outlast several cars. The pump has a cut-off which can be closed in case the check valve does not hold well.

As far as the system is concerned, if anyone wants something very cheap he can get a 25 cent bicycle pump and fit it to the dash. This is not quite so neat, the pump being a little longer, and the shortest pump that can be found should be used. The litthe brass pumps above referred to cost from \$1.50 to \$3.

If Mr. Corbin was as fond of the steamer as I am he would have no hill trouble. We do most of our pleasure driving over the mountains, about 5 miles from my home, as we find it much more pleasant to drive over the wooded mountain roads than over the fine level State roads running through the valley where we live. There is a sameness about this road, and it is about the hottest place one can find to drive. With a good steamer the hills are no obstacle, and such a car will travel over mountain roads all day long with perfect ease. As stated above, driving under these conditions is much more enjoyable than to drive on the J. HARRIS WIGHT. hot State roads.

# Electric Searchlights. Editor Horseless Age:

I have read the articles concerning electric lamps for autos which have appeared in your paper with considerable interest. I note that some makers of electric equipment furnish silver parabolic reflectors to replace mirror lens reflectors. I understand, however, that naval searchlights use mirror reflectors. Can you inform me through the columns of your paper which is the most efficient for electric searchlights? Would an electric lamp, with its socket screwed in place of the gas burner and its filament the same height as the flame, be in exact focus with the mirror?

[We cannot tell you whether the parabolic reflectors or lens mirrors are the most efficient. One reason why silvered parobolic reflectors are not used with electric arc lights and acetylene lights is that they would not stand the heat.

J. T. L.

The focus of a parabolic reflector is a point, and since an acetylene flame and a tungsten filament both have considerable dimensions, they cannot be in the exact focus of the lens. But presumably the acetylene burner was adjusted so the central point of its flame coincided with the focus, in which case the electric light will also be properly focused.—ED.]

# Two Cylinder Crank Construction. Editor Horseless Age:

I would like to ask the following questions, to be answered in your columns. In building a two cylinder, vertical, four cycle motor, are the cranks placed opposite so as to balance the reciprocating parts, or do they place them both on one side and have the impulses at equal intervals?

What are the objections to the friction transmission?

T. P. CHASE.

[Both constructions of two cylinder cranks are used, but that with crank pins opposite seems to be most popular at present. A double cylinder vertical engine with both pistons moving up and down together will vibrate very strongly, unless some special balancing method, like that on the Oakland two cylinder cars, is employed.

The chief objection to friction transmission is that it is not positive. Another objection is that wear of the friction surfaces is rather rapid, but this objection is reduced in importance by the fact that the friction materials can be renewed at slight cost.—ED.]

# The Enameling or Baking Process for Finishing Automobile Bodies. Editor Horseless Age:

Practical men are becoming aware of the fact that the all metal body as used on automobiles and railroad cars demands some different method of finishing than that which has so far been used for all good coach or car bodies. The considerable time required in the ordinary process for the different coats to dry is the cause of much delay in getting out work, and also requires increased floor space for keeping the work moving.

Some of this floor space might be set apart and fitted up with steam pipes or some other arrangement for heating it to a temperature of 160° Fahr. The space should be large enough to hold one day's work. Grind the color in a good grinding varnish bought in paste form and mix with a good mixing varnish to form an enamel that will bake in from nine to ten hours at a temperature of 160° Fahr. One day's work would then be ready the next morning for the next application, and a great deal of time could be saved. All of the different operations, viz., coloring, rubbing, varnishing and even finishing, could be carried out in this way, and the result would be a finish that would outwear work done by the present method of painting and f.n-

I do not mean to fit up an oven or a kiln, but to set apart a large room with ample floor space, entirely closed except for ventilating openings, so that as soon as an operation on the body is completed the body could be run into this room. At night the heat could be turned on to produce a temperature of 160° Fahr., and the next morning you would find your work ready to receive another coat, the coat applied the previous day having been baked hard and tough.

Some may object to the large amount of floor space required for the drying or baking room, but it must be remembered that where this process is applied the bodies need not be left standing idle for forty-eight hours for the varnish to dry (and in damp weather the different coats will not properly dry even in this time).

Where the baking process is to be applied an entirely different class of varnishes from those commonly employed must be used, varnishes especially made for the baking process. If any reader of THE HORSELESS Age is interested in the method I will try to answer any reasonable inquiry.

U-No.

# Formula for Steering Pin. Editor Horseless Age:

Please give formula for finding correct diameter of front axle spindle bolt for a four cylinder touring car of standard type. Weight of car empty, 2,800 pounds. Bolt will be made of machine steel, case hardened.

J. T.

[We have never seen a formula for the size of this pin, but we would go about its calculation in the following manner: From the section of the axle just outside the spring pad and the tensile strength of the material determine what force would be necessary, applied at the centre of the pivot pin, to bend the axle in a fore and aft direction. Then make the pin of a diameter so as to have a shearing strength equal to one-half this force, if the axle spindle is midway between the two shearing points. If the axle spindle is nearer to one of the shearing surfaces the diameter must be made slightly larger, as the strain is then not evenly divided between the two sections of the pin.—ED.]

# Where Autos Are Barred on Market Days.

Some American automobile tourists who recently made a tour to Nova Scotia had the misfortune to come in conflict with the local regulation which prohibits the driving of automobiles on public roads on market days. The tourists discovered, too late, unfortunately, that market days are not the same in the different towns, and while they steered clear of the market day regulation in one town they came in conflict with it in another.

Baron Boto, Japanese Minister of Communications, is looking into the advisability of introducing motor mail delivery in the principal cities of Japan, and also in some of the remote districts.

# GARAGE ITEMS

# Recording Garage Cash Sales.

By W. V. W.

Keeping track of the cash sales made on the floor or in the stockroom is one of the most difficult problems in the management of a large garage. Though most of the cash sales represent minor items, their aggregate will foot up a good sized total at the end of the month, and the fact that, as a rule, more than one person takes in the money for the cash sales leaves the door open to confusion, loss of money, of time and of customers.

Since the occupation of the establishment's new building the superintendent of the White Garage. Los Angeles, has introduced a system of recording cash sales that has given good results. Whether the item sold is gasoline, oil, labor or accessories, a duplicate bill is made out, one of which goes to the buyer and the other one to the bookkeeper. The bookkeeper's copy remains on a hook alongside of the desk or portable oil tank until evening. All the bills are numbered. Whenever a cash sale is made the man receiving the money records the amount on the cash register, at the same time writing the number of the bill. the amount taken in and his name on a pad provided for the purpose. On the cash register four buttons for four different classifications of the sales have been provided.

The buttons divide the cash record into four columns, headed "Garage," "Gasoline," "Oil" and "Stock." If gasoline is sold the foreman, after making out the bill, presses the button marked "Gasoline," and the amount of the sale and registers the transaction. The machine automatically records the sale in the "Gasoline" column. Other items are recorded similarly, thus making it possible at the end of the day to ascertain the amounts of cash received from the four classes of goods at a glance.

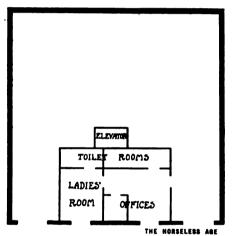

Under the head "Garage" the following items are entered: Washing and polishing, all garage labor, storage, carbide in less then 10 pound cans, changing casing or tube, towing, driving services and auto hire. The gasoline column includes distillate, and coal oil is classified under "Oil." "Stock" sales comprise carbide in 10 pound cans, grease, tires and other parts out of the stockroom.

In the stockroom a similar system has been introduced. The four classes registered separately on the cash register are repairs, white parts, local parts that are bought outside or made in the shop, and C. O. D. sales, though items in this last class are not added to the total of the other three.

For reference purposes the superintendent of the garage has started an alphabetical double index of owners' names and card numbers in order to facilitate the identification of cars by the names of the owners or by their numbers. Every car entering the garage is recorded on two separate cards. On one card the name of the owner appears, followed by his address and telephone number, with the number of his car on the other side of the card. The second card reverses the order of the entries, the car number coming first and the owner's name last. By reference to this double index the owner of a car of any number can be ascertained without loss of time, and with equal ease the name of the owner will disclose the number of his car.

### The Uptown Garage.

The building at 144 to 160 West Twenty-fourth street, New York city, is being entirely remodeled and will shortly be opened as the Uptown Garage. It is a five story and basement structure 100 feet square. There are two doors in the front, one near either end, to be used as entrance and exit respectively. Between these doors are the offices and ladies' waiting room, with toilet rooms in the rear. Lockers are provided in

FIRST FLOOR PLAN OF UPTOWN GARAGE.

the men's toilet room for those who drive their own cars. The elevator, which will take a car from the basement to the fifth floor in thirty seconds, and can be entered from either side, is located back of the offices in such a position that both in entering and leaving the car makes a turn of 90 degrees. The central position and double end feature of the elevator make turntables unnecessary.

On the second floor are the chauffeurs' rooms, with lockers, etc., and the fifth floor is to be a very complete machine shop, with facilities for making any repairs. The shop will be in charge of Mr. Egley, who has had seven years' experience in one of the repair shops in the city. The basement, first, second, third and fourth floors will be available for storage except for the offices, and five washstands will be provided, two on the main floor and one each in the basement and on the third and fourth floors. There are two gasoline tanks of 275 gallons capacity each, provided with Bowser pumps. G. M. Irwin is manager, J. C. Waterson president and J. W. Hatch vice president.

### The Belnord Garage.

A new garage is at present being erected at 260 West Eighty-seventh street, New York city, just west of Broadway. This is a residential section at the extreme north end of the automobile district. It is to be known as the Belnord Garage, and will care for gasoline pleasure cars exclusively. The front of the building measures 125 feet, and is of glass for the first and second floors. The building is 1081/2 feet deep, with two full floors and a third floor about 25 feet square. There are two entrances to the first floor, one near either end of the front, and the second floor is reached by an elevator situated at the centre of the front and entered from the street. The walls are of brick and the floors of concrete. The building will be supplied with electric light and steam heat. The central part of the front will be occupied by the offices, 30x20 feet, part of which will be fitted up as waiting room and part as private office.

A machine shop will be situated at the rear of the second floor, where skylights are provided. The shop will be 30x50 feet and will be provided with two pits and a complete set of machinery for doing all kinds of repair work. A stock room 35x60 feet will be in front of the machine shop. Practically all the rest of the first and second floors, or about 23,000 square feet, will be available for storage.

Two washstands will be provided on the first floor and three on the second. They will be of the revolving type with light in the top. Provision will be made for heating the washing water in winter. The third floor is to be devoted entirely to the chauffeurs' rooms, where billiard tables will be provided, as well as shower baths, lockers. etc. There will be five five-barrel gasoline tanks in the courtyard at the rear, provided with air pressure pumps. The gasoline will be taken to the cars in three portable tanks. The stock of oil will be kept in a small separate room on the first floor, where several grades will be carried. A compressed air plant will be provided and the air will be piped to all parts of the first and second floors, twelve outlets being provided for the inflation of tires. Exceptional precautions are to be taken against fire. The garage will be provided with automatic sprinklers, sand barrels and hand extinguishers, and it is planned to organize the force into a fire brigade and to have twenty hands in the building at all hours ready to answer the automatic alarm. The cars will be checked in and out, and a record will be kept to guard against unauthorized use of cars by the chauffeurs.

# Maintenance Under Contract.

The Cordner Motor Car Company, of 1540 Broadway, New York, who have the metropolitan agency for Acme cars, have been conducting a maintenance service since early in the year, by which owners of their cars are relieved of all worry and trouble incidental to the care and repair of the car, at a cost which, it is believed, is less than

the expense which would be incurred if the owner were to give the matter his personal attention. For the sum of \$200 per month the Cordner Motor Car Company agree to store and care for the car for the period of one year, furnishing a chauffeur, tires, gasoline, oil and other incidentals, executing all necessary repairs, replacing any parts which may fail, and, in short, fully assuming the maintenance of the car, so that all the owner has to do is to order the car sent around when he desires to use it. Credit is given for supplies purchased on short trips, such as the week end outing, but when an extended tour is made the time during which the car is away is deducted from the maintenance period. Damage to the car, due to accidents or ill usage on the part of the owner, is made good at his expense.

To secure this rate a contract must be entered into for a year's maintenance, and the rate is based upon an assumed travel of 1,000 miles per month. If the actual mileage is less the customer is credited with 10 cents per mile for the difference, and if the mileage exceeds this figure he is charged 10 cents per mile for the excess mileage.

The chauffeur is hired by the Cordner Motor Car Company, but is subject to the owner's orders when the car is in service. So far, this divided responsibility of the driver has not led to any trouble.

At the expiration of the year's contract, and before another contract will be signed by the company, the car must be given a thorough overhauling, the labor cost of which the owner must pay, but any new parts necessary through defect are supplied at the expense of the makers of the car.

# New Building for Seattle Winton Branch.

Quite an imposing building is at present being erected by the Winton Motor Carriage Company for its Northwestern branch in Seattle, Wash. It is a six story, basement and sub-basement structure, fronting 80 feet on Pike street and 110 feet on Terry avenue, and will call for an investment of \$150,000 it is said. The building is expected to be ready for occupancy about December 1, and immediately upon its completion the Winton branch will be removed from its present location at 715 East Pine street and occupy the entire building.

The plans for the new building are the work of Geo. W. Miller, manager of the Northwestern branch. They embody a number of novel features in garage construction. The roof of the building, which has a surface area of 8,800 square feet, will be used for testing purposes, which arrangement offers the advantage over an indoor testing room that no annoyance will be caused by the exhaust gases and the noise. In the centre of the building there will be a spacious court, which will permit of easy manœuvring of the cars. The garage space will be divided up according to the separate stall plan, and as soon as an owner ar-

rives with his car it will be received by a foreman, who will place it in its stall. Large lockers are provided for the convenience of patrons, and for the use of owners who drive their own cars there will be a special department where they can make their own adjustments and repairs without being disturbed. The building also will contain a very completely equipped machine shop and a stockroom in which renewal parts of all kinds will constantly be kept on hand.

The main floor will contain the executive offices and salesroom. On the upper floors there will be an upholstering department and a paint shop. Among other features of the new garage building is a clubroom for chauffeurs, which will be equipped with billiard and pool tables and a supply of trade papers, where chauffeurs can spend their leisure hours while waiting for orders from their employers. A private branch telephone system will be installed, connecting all the different departments with the main office. Up to now most of the salesrooms and garages in the Northwest have been housed in old buildings not specially adapted for the purpose, and the new Winton garage marks probably the first step toward the erection of a series of buildings specially for the automobile trade.

# Garage Fires.

The garage of the Robbins Auto Company at Owosso, Mich., was nearly destroyed by fire on the night of August 23. The blaze spread so rapidly that there was not time to remove all the autos and several were badly damaged. The loss on the building is estimated at \$10,000.

A blaze was started in the Burker garage in Racine, Wis., on August 23, owing to gasoline accumulated in the drip pan underneath the machinery of a car becoming ignited in some way. The flames spread rapidly, but the car was promptly pushed out into the street where the fire was extinguished with sand.

# Hoyt Instrument Company to Build Salesroom and Garage.

The Hoyt Electrical Instrument Works have bought a piece of land fronting 100 feet on Main street, Penacook, N. H., which forms part of the Central Trunk Boulevard being built through the White Mountains. The company will erect a modern fireproof garage and salesroom on the plot. The Washington street plant will in future be devoted exclusively to the manufacture of Hoyt meters.

# Take Up Manufacture of Auto Bodies.

The Kahler Company, of New Albany, Ind., have taken up the manufacture of special automobile bodies, that is, bodies built to suit the requirements of automobile manufacturers. They have just completed a new and modern plant, with electric power. The new plant is so situated as to enable it to ship its products by four railroads.

# Swinehart Company to Manufacture Pneumatics.

The Swinehart Clincher Tire and Rubber Company, of Akron, Ohio, are planning to embark in the manufacture of pneumatic tires and to carry on a more extensive selling campaign in the future. The company have recently sold the remainder of their treasury stock, and will immediately proceed to improve their equipment and enlarge their capacity. A pneumatic tire is at present being developed, and an improvement in the company's solid tire for commercial vehicles is being tested out. At the annual meeting of the company, held on August 23, the following officers were elected: J. A. Swinehart, president; W. W. Wuchter, vice president and general manager; C. O. Baughman, secretary, and R. A. May, treasurer. President J. A. Swinehart will start on a European trip about October I, with the object of establishing a European branch. Mr. Wuchter, who has been general superintendent of the Firestone Tire and Rubber Company for the past five years, will assume the active management of the company's affairs.

# Studebaker Business in Colorado Incorporated.

The Studebaker interests in Colorado have been incorporated with a capital stock of \$100,000 under the name of the Studebaker Colorado Vehicle Company. The company owns a repository for carriages and wagons at Fifteenth and Blake streets and a garage and automobile repository at 1532-38 Broadway, Denver. The officers of the company are: Frank S. Fish, South Bend, Ind.; W. S. Hunnewell, Denver, vice president, general manager and treasurer, and Elias K. Pound, Denver, secretary. The management of the Denver stores will continue in the hands of W. S. Hunnewell, who has been at the head of the business for four years.

# Mason Automobile Company to Remove to Waterloo.

It has finally been decided to remove the business of the Mason Automobile Company from Des Moines to Waterloo, Ia. The capital stock of the company will be increased to \$1,000,000, and the car will hereafter be known as the Maytag-Mason car. The company has bought the plant of the Waterloo Motor Works, formerly owned by the Cascaden Manufacturing Company, which was specially erected for automobile construction. The company expect to move into this factory on October 1, and to be in full operation within thirty days. In addition to this building they will immediately erect a three story glass and concrete building, 100x200 feet, and a special office building opposite the present factory building. It is planned to continue the manufacture of the company's double cylinder opposed 5x5 inch car, and to turn out 2,500 of this type in 1910.

# Commercial Applications.

# The Taxicab Business in Kansas City, Mo.

By J. W. Morrison.

The taxicab business is of such recent origin in Kansas City that it may truly be classed as an infant industry. The pioneers in the enterprise here were two young men, who bought one taxicab last winter and operated it in a free lance style in the hotel and business district. Their enterprise proved so profitable that it was not long before rivals entered their virgin field, and there are now two regularly formed companies competing for the business.

The larger of these two concerns is the Standard Taxicab Company, which was organized April 15 last. This concern has offices at 1329 Walnut street, which is close to the business centre of the city. The other concern, the Balch Taxicab Company, has its place of business at 1912 East Thirteenth street, well out into the residential district.

The Standard Taxicab Company operates two makes of cabs, viz., Thomas and Carter. The company is at present operating twelve machines, six of each make. This number is not sufficient to fill the rapidly growing demand for taxicab transportation, however, and the company now has orders placed for twenty-five more machines, which are to be delivered as rapidly as the manufacturers can supply them.

The Standard Company maintains two public stands, one at the Sexton and one at the Savoy Hotel, and also one private stand. By far the greater part of the firm's business, however, is through calls for service turned in over the telephone at the company's main office.

All the cars in Kansas City use pneumatic tires. The Standard Company uses Goodrich quick detachable tires. No extra wheels are carried by its cars. The company has two systems of charging, one by the hour and the other by the meter. The rate by meter for one or two passengers is 40 cents a mile. Waiting time is charged for at \$1 per hour. On week days all charges are made according to the meter, but on Sundays there is an extra number of calls for rides over the boulevard system, and then the cabs are rented out by the hour. The rate is \$2 an hour if only one or two passengers are carried, and \$3 an hour when more than two are carried.

All the taxicabs used here have the meters attached to the front wheels. The Standard Taxicab Company makes its repairs in its own shops, but has a maintenance contract with the tire makers. The records of the Standard Taxicab Company show that its cars make a daily average of about. 25. Frequently some of the cars

have more than 30 miles to their credit. The operators are paid a regular salary.

CLASSES OF PATRONS.

The records of the Standard Company show that the calls for service can be divided into three general classes-social calls, that is, calls from persons who wish to go to balls, receptions or theatres, or to fill dinner engagements. This is by no means a small part of the business, and is one that is catered to, as it is profitable and easy work for both the cabs and the operators. Next come the depot calls. These are both from the hotels and from private residences, and are from persons who usually are in a hurry to catch a train and are anxious to make good time. Right here it may be mentioned that Kansas City has, as yet, no police regulations leveled directly at the taxicab as such, and the operation of the cabs is controlled solely by the regular motor car regulations. The third class of patronage is from the men about town in search of amusement; in other words, from the "joy riders." This class of business comes almost entirely after the shades of night have fallen, and the owners of taxicabs gain no small pecuniary profit from those who like to 'hit it up a little" while the rest of the town is

#### SIGHTSEEING TRIPS.

There is one source of business for taxicabs in Kansas City that probably is not available in all other cities, and that is the park and boulevard system. Kansas City has miles and miles of boulevards, all of them connecting and leading to natural parks. These boulevards, paved with macadam and rendered absolutely dustless by applications of crude oil, make a paradise for motorists. The man who doesn't own a car takes advantage of the fine motoring by hiring an automobile or a taxicab, and this class of business keeps the taxicabs busy from morning till night every Sunday. Much of this business, of course, is from strangers in the city. The manager of the Standard Company says that an astonishing number of visitors in the city have heard of the fame of Cliff drive, a boulevard that has been cut out of the side of a high bluff overlooking the Missouri River, and ask to be taken over it. This particular drive is several miles from the depot and hotel district, and is itself 3 miles long, so that it will be seen that boulevards are a good asset to the taxicab man when it comes to registering profits on the cab's meter.

In this connection it may not be amiss to say, however, that Kansas City is an expensive town in which to run a taxicab or any other kind of a motor car, because it is a city of hills. In fact, there is scarcely a moment when you are not going either up or down, which means that if the motor is not doing its best the brakes probably are working overtime. So hilly is it that the manager of the Thomas Company, when he came here to install the Thomas taxicabs, said it was the hardest city he ever saw to operate a taxicab in.

DIFFICULT TOPOGRAPHICAL CONDITIONS.

The difficulties presented by Kansas City's topography are so numerous that when autombiles first came into use in the East it was freely predicted that they would never be seen on the streets of Kansas City, because they would not be able to negotiate the grades. However, since those prophecies were made Kansas City has grown into one of the largest distributing points in the country for motor cars.

The Balch Taxicab Company, the other concern here, operates two taxicabs of Overland make. This company devotes itself entirely to answering calls for social purposes, and finds that it is kept busy by that line of patronage. The Standard Company intends to invade the residential district soon, and for this purpose will establish a garage on one of the boulevards in the southern part of the city, probably about Linwood boulevard and Troost avenue. This will enable the company to respond to residence district calls without the loss of time involved in sending a cab clear from the business centre of the city.

### The Taxicab Situation in St. Louis.

The taxicab business in St. Louis, Mo. is practically controlled by one company, the St. Louis Taxicab Company, which maintains an office at 5011 Delmar avenue. and a garage and repair shop at 1622 Morgan street. This concern entered the taxicab field in March of this year with one Atlas cab, and has gradually increased its stock until now it has fifteen Atlas cars in commission. The management states, moreover, that it expects to continue to increase until it has 100 cars in service, and that it is its intention to have fifty cars in service by the first of the year.

Although St. Louis never was much of a cab riding city, when the taximeter cabs were placed in service there arose immediately a constant demand for this type of transportation. Persons who never used horse drawn cabs are now regular patrons of the taxicab. Stands are maintained at the following hotels and clubs: Maryland, Southern, American, Jefferson, Marquette and Planters hotels, and Missouri Athletic and St. Louis clubs. At present the company can keep only one or two cars on any of the stands at one time, but as they increase the number of cars in service more cars will be placed on the various stands. No special charges for licenses are made by the city for the operation of the cabs, the latter being licensed the same as any touring car owned by an individual. The Franco-American taximeter is used, and is attached to one of the front wheels. Diamond quick detachable rims are fitted to all cars, and no extra tires are carried. Drivers are hired on a straight salary basis. The average daily mileage of the cars is about 50. All repairs are made in the company's own shop, where several expert machinists are employed. The rates are so cents for the first mile and 10 cents per each additional quarter mile for one or two passengers. For three or four passengers a charge of 70 cents is made for the first mile and 15 cents for each additional quarter mile. These rates are somewhat higher than the rates charged in Eastern cities. Ten cents is charged for each six minutes of waiting, and a flat rate of \$4 an hour is made if desired.

In addition to the cars operated by this company there are probably seven or eight touring cars, with taximeters attached, owned by individuals, for rent, and also four other taxicabs in the city. The individual car owners charge the same fares as the company.

#### Automobile on Railroad Tracks.

To reduce the cost of carrying passengers over a standard gauge branch railroad built for the purpose of carrying coal from a mine in the Coast range of California, a six cylinder touring car, equipped with six flanged wheels, is to take the place of the locomotive and passenger coach. The automobile, a Premier, has been fitted with the flanged wheels and the extra pair in front in a Los Angeles garage. Trial trips over an experimental track have given satisfactory results, but only actual use can demonstrate the practicability of the scheme on the grades and curves of the mountain road.

The automobile is to run over a branch line starting at Chanslor, on the Coast line of the Southern Pacific, and ending at the mines of Stone Canyon, 22 miles distant in the hills of the Coast range. Both settlements are in their infancy, and passenger traffic is light. In order to make possible faster and more frequent service at reduced cost Walter Chanslor, the founder of the town bearing his name, and member of a Los Angeles automobile firm, conceived the idea of changing a touring car into a self propelling passenger coach.

# Another New York Suburban Express Service.

• A single 3-ton gasoline motor truck is being run on general express business between New York city and Newark, N. J.. by the Duckworth-Crawford Express Company, 218 Duane street, New York. Two trips are made daily, and when the truck is out of commission or when there is too much freight for it to handle, horse-drawn trucks are hired to help out. The rates charged for freight between New York and Newark are 25 cents per 100 pounds. The service has been in operation only about eight months, and we are unable to get any data on cost of operation.

### Commercial Notes.

A company is being organized at Fremont, Ohio, to establish an automobile service between Fremont and Greenspring.

The City Council of Pasadena, Cal., has purchased two runabouts, at \$500 and \$600, respectively, for the use of the street superintendent and the city engineer. The

cars were bought from the Hanson & Whitman Company, a local concern, and are guaranteed for one year.

Harry E. Pence, of Minneapolis, Minn., who planned to establish a taxicab service in that city, announces that he abandoned the project because of the speed limit of 15 m. p. h. on parkways.

The Autocar Company have just delivered ten new Type 18 taxicabs to the Pennsylvania Taxicab Company, and have also received an order for additional cabs from the Taxicab Company of Baltimore.

The Maxwell-Briscoe Company, of Philadelphia, have just started six model H taxicabs equipped with 30x4 Ajax tires. Rates are standard for the city. Manager Roberts states that additional cabs will be put on soon.

The Automobile Transit Company, which conducts an automobile service between Reading and Bernville, Pa., has recently put in service a new 80 horse power, twenty passenger car, which covers the distance of 13½ miles in a little over an hour.

W. A. Quillin, a former livery man of Russellville, Ala., plans to establish an automobile line between Russellville and Tuscumbia, a distance of 18 miles. Mr. Quillin intends to purchase several touring cars and make two round trips per day.

The Seattle (Wash.) Taxicab Company now has thirty-five taxicabs in service, which are being much used, particularly by visitors to the A. Y. P. Exhibition. The minimum fare is 30 cents for a half mile, which is less than is charged in most other Western cities.

Gen. Ernest Coldwell and S. P. Kirkpatrick are organizing a company in Shelbyville, Tenn., for establishing an automobile service between Shelbyville and Fayetteville, by way of Lynchburg. Two cars will be placed in service, so constructed as to permit of carrying both passengers and freight.

Having experimented successfully with trucks of smaller capacity, the Polk Milk Company, Indianapolis, has purchased a 4 ton gasoline truck, which it will place in country service, collecting milk. The company expects to cover a route of 75 miles daily, between Indianapolis and Greenwood, Mooresville and Plainfield.

Several automobiles are to be used in connection with the new R. F. D. route out of Pullman, Wash. The rural route as established leaves Pullman on the Wawawai road and runs to Ontario, thence to the Ryan farm, up Union flat and return to Pullman from the south. The route will be 25 miles in length,

The services of the Pioneer Motor Company, between Marquette and Ishpeming, Negaunee and Presque Isle, Mich., are reported to have proven quite successful. Up to August 20 the cars of the company had carried 9,721 cash fare passengers, exclusive of 700 persons who made up charter parties, which chartered the cars at a flat rate. So far there has not been a single accident on the routes.

#### More Favorable Freight Rates.

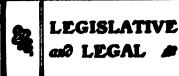

After October 1 shipments of single automobiles will be charged for by the railroads on an actual weight basis instead of on the basis of fixed minimum weights. Heretofore the railroads have charged 8,000 pounds at first class freight rate for any passenger machine with wheel base exceeding 86 inches. As many, and perhaps most, of the low priced machines nowadays have a wheel base exceeding 86 inches, there has been much complaint against this charge. The advantage claimed for the new arrangement is that it insures a more equitable distribution of the transportation charges, so that the smaller machines will hereafter be taken at the equivalent of 5,000 pounds at first class, and the charges increased only as the weight, size and value increases, the point being made that automobiles are of substantial and varying weights. A similar change will be made on shipments boxed or crated, on which the actual weight will apply, instead of the fixed minimum weights heretofore applied according to the size of the packages. The new classification affects shipments originating in the Northern States east of the Mississippi River, thereby including practically the entire manufacturing

A similar arrangement was made with Western and Southern railroads some time ago.

The automobile industry is represented in such matters by the general traffic department of the National Association of Automobile Manufacturers, Inc., and by arrangement between the associations, the general traffic department also represents the Association of Licensed Automobile Manufacturers and the American Motor Car Manufacturers' Association, with J. S. Marvin as general traffic manager, factory traffic managers co-operating under this plan on matters of general interest. This department is in touch at all times with the transportation charges on automobiles and parts throughout the country, Mr. Marvin attending meetings of railroad rate committees at various points.

# Schedules of Twentieth Century Manufacturing Company.

Schedules in bankruptcy of the Twentieth Century Manufacturing Company, bicycles and auto lamps, of 19 Warren street, New York, show liabilities of \$63,201 and nominal assets of \$23,837, consisting of stock, \$6,000; machinery and fixtures, \$1,000; motor boat, \$1,000; accounts, \$13,211; cash, \$2,-626, and twelve patents pledged to the Scoville Manufacturing Company, of Waterbury, Conn., a creditor for \$9,676. Among the creditors are George B. Wilson, Philadelphia, \$22,762; Merchants' Exchange National Bank, \$11.400; Leo Popper & Son, \$1,488; Manhattan Brass Company, \$845, and W. B. Bertels, Son & Co., Wilkes-Barre, Pa., \$800. The company owes \$670 for business taxes in New York and New Jersey.

246

### Parcels Post and Motor Mail Delivery.

Another bill designed to establish a parcels post has recently been introduced in Congress and will probably be taken up at the next session. It is known as House Bill No. 10,762, and was introduced by Hon. William S. Bennett, of New York, June 17. This bill provides:

First, for a general merchandise service in unscaled parcels at a cent per a ounces, the old merchandise rate of 1874.

Second, for a local unsealed parcels service at a cents for 4 ounces, z cent each additional 2 ounces—the general sealed parcel or letter rate of Great Britain.

Third, for a local service on the rural routes all mail matter in one class, with rates as follows: Parcels up to 1x6x12 inches, one-twenty-fourth of a cubic foot in bulk, and up to 1 pound in weight, 1 cent.

Larger parcels up to 6x12x12 inches, one-half the ordinary suit case or to one-half a cubic foot in bulk and up to 11 pounds in weight, 5 cents.

Larger parcels up to 6x12x24 inches, or to the size of the ordinary suit case or 1 cubic foot in bulk and up to 25 pounds in weight, 10 cents.

Fourth, for the insurance of all mail matter-

Pourth, for the insurance of all mail matter the ordinary rates to carry insurance up to \$10; the \$ cent registration fee to insure up to \$25; 2 cents additional for each additional \$50 to insure up to the full value of the parcel.

It seems to us that the plan to establish a parcels post deserves the support of automobile interests. If a low rate is made on parcels it is to be expected that an enormous business will develop in a few years. The delivery of the parcels by letter carriers on foot would be out of the question, and the introduction of motor mail and parcel delivery would be practically assured. This would create an enormous market for cars-a steady, permanent market, as the rural free delivery service is rapidly expanding. This, however, would not be the only benefit which a parcels post would confer on the auto industry. In order to insure the prompt delivery of parcels in the country the year around it would be necessary to build improved highways, and as it is the farming population that is most interested in the parcels post, the establishment of this service would tend to bring the farmers in line for good roads. At present the cry is often raised in the country that good roads benefit no one but the automobilist. It is quite conceivable that when daily mail delivery by automobile to every farmer's door becomes a reality this cry will cease.

### Senator Alids Promises New Auto Bill.

Senator J. P. Allds, of New York, whose automobile bill introduced in the last Legislature was vetoed by Governor Hughes, announces that he will introduce another bill at the coming session which not only will cover the taxation of automobiles, but

also impose proper limitations on the operation of the vehicles for the protection of the public. Mr. Allds asserts that the public has a right to demand that all persons in charge of automobiles shall be competent, from the mechanical standpoint, to drive the machines, and also be mentally competent to be in charge. Senator Allds states that chauffeurs should be licensed, and that in case of an offense against the law the magistrate should make an indorsement on the face of the license. If a man is proven to be wilfully negligent or persistently careless, his license should be revoked.

### A Decision Regarding the Scope of Automobile Guarantees.

George A. Joslyn, an Omaha, Neb., newspaper man, some time ago brought suit against the Cadillac Automobile Company to recover \$3,217.87, paid for a car of the company, and \$66.50 paid for freight charges, because the car delivered to him would not climb the Farnam street hill, so Joslyn alleged. The Circuit Court at Detroit, after hearing the case decided that, since the company did not specifically guarantee the car to climb this particular hill, the complainant was not entitled to damages. Joslyn has now appealed to the United States Circuit Court of Appeals.

# Coroner's Finding in Indianapolis Fatalities.

Coroner Blackwell, of Indianapolis, upon concluding his inquest into the deaths of William Bourque and Harry Holcomb, driver and mechanic, respectively, of the Knox car that was wrecked in the races on the Indianapolis Speedway, on August 19, holds the officials of the Speedway responsible and recommends an investigation by a grand jury. The coroner says that the fatality was due to the car striking an open ditch, near the edge of the track, which was 20 inches wide and 2 feet deep. He also calls attention to the fact that the management of the Speedway had an ambulance force on hand, from which he concludes that they expected an accident.

#### Garage Restrictions in Washington.

Acting Engineer Commissioner Kelly, of the District of Columbia, has made an amendment to the building regulations of the District, prohibiting the establishment of a public garage without the consent of 75 per cent. of the property owners within 200 feet of the proposed structure if on a residence street, or without the consent of two-thirds of the property owners within 90 feet if on a business street adjoining at the rear residential property or a public alley.

#### After Indianapolis Joy Riders.

The board of public safety and Judge Whallon, of the Police Court in Indianapolis, have collaborated in a plan to stop joy rides and unusual violations of the motor laws. Last week Judge Whallon fined Dolph Staub, a driver for E. L.

Patrick, \$180 and costs and sentenced his to therety days' imprisonment for malicing trespass, and also fined him \$10 and cost for violating the speed laws. The saley board has announced under a new ordinance it will not permit the registration of driven who have been given workhouse sentences. Staub wrecked his employer's machine when he took a number of friends riding.

#### Joy Riding Now Larceny in New York.

Section 1239a of the Revised Statuss of New York State, which went into effect September 1, makes joy riding a larceny, providing that those who borrow annon-biles without the authority of their owner have stolen them and are liable to punishment accordingly. By another amendment to the automobile law a person who with intent damages an automobile or other motor vehicle is declared to be guilty of a misdemeanor.

### Jeffery Will Fight Oil Inspection Law.

Thomas B. Jeffery & Co., of Kenosha. Wis., one of the largest automobile mamfacturing concerns in the West, will test the constitutionality of the oil inspection law passed at the last session of the Wisconsin Legislature. The company has refused to pay a bill of \$7.60 from H. E. Grace, deputy oil inspector, for inspecting 76 barrels of gasoline.

# Officials Ignorant of Law, Release Offender.

Postmaster W. L. Irvine, of Harpers Ferry, W. Va., was arrested at Chambersburg, Pa., for not having a Pennsylvania State license tag number on his automobile. Mr. Irvine contended that under a new law a person can ride for ten days in Pennsylvania without a license. As the officials were unable at the time to get hold of a copy of the law they released him. Afterward they discovered that the law does not go into effect until January 1, and then only with States that reciprocate. Non-residents driving in Pennsylvania this year must take out licenses, the same as before the new law was passed.

#### Legal Notes.

An ordinance to provide and compel the use of mufflers on automobiles excepting when the machine is developing full power to climb a hill has been introduced in the common council of Beloit. Wis.

The police of Kenosha, Wis., have been instructed to arrest all automobilists who exceed the speed limit on the main thoroughfares of the city. There have been few prosecutions for speeding this year.

City Commissioner W. J. Kohlhauff, of Houston. Tex., plans to introduce an ordinance in the City Council to regulate the conduct of automobile garages. A similar ordinance was recently adopted in San Antonio, which seems to have suggested the idea to Commissioner Kohlhauff.

# OUR FOREIGN EXCHANGES

### The Tire Business in Germany.

A recent article in the Gummi-Zeitung throws a number of interesting sidelights on practices in the German automobile tire business. A translation of the article is as follows:

The rising price of crude rubber compelled our industry to raise prices, beginning in the usual manner with mechanical rubber goods. In the camp of tire manufacturers it is, however, as yet rather quiet, and it is a matter for surprise that the tire prices were not raised first, as much greater quantities of rubber are consumed in their manufacture. The chief reason is that in many cases bicycle tires and automobile tires of both the pneumatic and solid variety are delivered under contract, in which case a price increase is impossible. Such contracts are made by dealers, either jobbers or garage owners, chiefly to secure the lowest-possible prices, and it is the custom to specify a number of tires which is to be taken in one year, but which generally is not taken. "Accommodation" has been a very familiar term and is constantly asked for by the dealers. As early as July and August, when business begins to get slack, the tire manufacturers begin to make contracts for the coming season. although oftentimes not even one-half of the tires contracted for the previous year have been taken. Here, again, "accommodation' becomes a factor, as the unfulfilled portion of the contract is either cancelled entirely or is included in the next year's contract. Even if a manufacturer proceeds in a proper manner and insists upon the delivery of the entire number of tires contracted for, he will not meet with success, for the dealer will always urge various excuses which to him seem sufficient to relieve him of his responsibility as regards carrying out the full contract.

Instead of doing business on a business basis, the manufacturers, unfortunately, are introducing the most varied practices, and grant favors whose detrimental influences in dealers' circles are clearly discernible when new contracts are closed. It has also become quite customary, even when no more than 100 sets of tires are contracted for, to brand them with any special fantastic trademark, instead of the regular factory mark. In this connection names are often selected which might be looked for anywhere else except on pneumatic tires. It is not impossible that during the coming summer Zeppelins will not only navigate the ethereal blue but will also ride the dusty road as Zeppelin tires, provided the owner of the name does not forbid the nuisance. It will be interesting to note how tire prices will vary during the coming summer in view of the present high

prices of crude rubber. Perhaps the present situation will result in an attempt being made to prevent such unnatural price fluctuation in the crude rubber market in the future.

A definite time guarantee is but rarely given on automobile tires, but the kilometer guarantee according to which the purchaser is made a certain allowance proportional to the difference in mileage guaranteed and actually obtained, which has long been customary in the solid rubber tire business, is also slowly being introduced in connection with pneumatics. The guarantee begins on the day of sale and covers a certain number of kilometers, generally either 5,000 or 6,000 kilometers for pneumatic tires and 15,000 kilometers for solid rubber tires, which must be covered in a single year. The manufacturer guarantees the tires to be free from defects and to be durable in case of reasonable use. Damage to the tires due to driving on newly surfaced roads is not covered by the guarantee. As soon as the tire develops a defect covered by the guarantee it is replaced by the manufacturer, the customer paying for the service he received from the defective tire.

It is, of course, a very difficult matter to keep track of the mileage of the tires, and, especially in the case of motor trucks, of the loads carried, and these matters often lead to disputes. The motor trucks of breweries are often overloaded, which is very hard on the tires and causes them to wear out prematurely. There is little complaint about solid rubber tires from omnibus companies, whose vehicles run principally on smooth asphalt pavements in the city, and for this reason the tires are naturally much longer lived. But in the case of these companies the operation of the vehicles is under constant supervision, which is not the case with the omnibuses.

German solid rubber tires have in recent years found quite a market in England, being sold, generally, on a mileage basis, and English customers are in the habit of placing contracts at fixed prices for years. Many rubber factories will undoubtedly suffer under these contracts with the present high prices of crude rubber.

# Status of the Austrian Automobile Industry.

A report concerning the condition of the Austrian automobile industry during the past year was recently presented to the Minister of Commerce by the Chamber of Commerce. It is pointed out in the report that the new motorist liability law had a strong influence on the business during the year. The ominous expectations attached to the new law deterred the public from purchasing automobiles. A change in this respect took place only toward the end of the year, after the automobile club had succeeded in making it possible for automobile owners to insure themselves

against liability at relatively low premiums. The demand for automobiles in Austria was still largely met by foreign firms. The overproduction in this line of industry in general had its depressing effect on the home market, as the foreign manufacturers, in order to accelerate business, quoted prices which were lower than the cost of production at the best home factories. The protection afforded by the tariff must be considered entirely insufficient. Of the new firms established in Austria during the last two years two have already disappeared, partly on account of insufficient sales and partly on account of unsoundness in the corporations themselves, which even at the time of organization did not promise continued success. In spite of the financially rather gloomy general view, it must, however, not be lost sight of that the Austrian industry is gaining in strength, especially in a moral sense, as home buyers are slowly recognizing the fact that Austrian automobiles are equal to foreign machines, and are also learning to appreciate the advantages arising from direct relations with home manufacturers in respect to fulfillment of guarantees, delivery of spare parts, repairs, There have been no revolutionary technical innovations during the year, which is undoubtedly to the advantage of the industry, and the efforts of the designers have been concentrated on the perfection of all parts so as to insure the greatest possible reliability, which is naturally a chief requirement of the buyer.

The suggestion has been made to exclude horse traffic from a large portion of the city of Westminster, England, on one Sunday late in the summer or early in the autumn, so as to give a demonstration of the advantages enjoyed by a horseless city.

A recent incident illustrates the important position which the automobile industry now occupies in the manufacturing world. A party wishing to contract for the production of a considerable number of special machines was unsuccessful in placing the order in either Chicago, Milwaukee or Cleveland, every shop of proper capacity to do his work being so busy on automobile work that it could not accept another contract for some time to come.

The Second International Good Roads Congress is to be opened at Brussels, Belgium, on July 31, 1910. The program of the individual sections has been laid down as follows: Section I.—Construction and maintenance of roads; erection of road signs; methods of dust treatment; completion of road systems; construction of local railways, etc. Also the care of streets in large cities, street cleaning, sprinkling and use of motor street rollers; removal of snow and ice, etc. Section 2.—Street traffic; influence of the weight and speed of vehicles; conditions which must be fulfilled by different types of vehicles, etc.

# The Brighton Beach Twenty-four Hour Race.

The second twenty-four hour race meet of the season was held at the Brighton Beach "motordrome," Long Island, on Friday and Saturday of last week. The event was won by a Renault car driven by Basle, who covered 1,050 miles, which is 127 miles less than the record made by Robertson on the same track last year. Second place was secured by the Rainier, driven by Disbrow, with 938 miles, and third by the Acme, driven by Patschke, with 883 miles. There were ten starters, as follows:

Car.	Drivers.		
ı-Renault	Basle and Raffalovich.		
2-P. & S	Lescault and Howard.		
3—Acme	Patchke and Maynard.		
4-Acme	Vantine and Koyouh.		
5-Lozier	Heina and Cobe.		
6-Stearns	Grosse and Mulford.		
7-Houpt	Robertson and Poole.		
8-A. & K	Hughes and La'well.		
9-Fiat	De Palmer and Parker.		
10-Rainier	Disbrow and Lund.		

The meeting was marred by numerous accidents, ascribed by some to the condition of the track. The twenty-four hour event began at 10 o'clock Friday night. Shortly, after 11 o'clock there was a collision between the Stearns car and Acme No. 3. The Stearns car struck the Acme, snapped its axle and turned over twice. The Stearns mechanic, Leonard Cole, met almost instant death, while the driver of the car, Laurenti Grosse, received injuries from which he died in the hospital the following day. The Allen-Kingston car, while driven by Hugh Hughes, had a collision with another car, whereby its gasoline tank was damaged and the gasoline spilled and set on fire, and Hughes was severely burned about the head. The Lozier, driven by Heins, crashed through the fence twice during the meet. The first time it turned over, but the driver and mechanic miraculously escaped unhurt, and after a delay of three hours continued the race. The second time the car went through the fence it turned over twice and was completely demolished, but the occupants again escaped serious harm.

Between 4 and 5 o'clock on Saturday morning a special policeman named Corrigan was badly injured through the overturning of a metal lamppost, which was knocked over by one of the racing automobiles, which skidded while going at top speed. Corrigan's leg was broken and his left knee dislocated.

The twenty-four hour event was preceded by a speed carnival, which included a one hour scratch motorcycle race, a six hour race for small cars, a 5 mile free for all and several exhibition runs. A note of discord occurred during the six hour race for small cars, in which two S. P. O. cars, a Hupmobile, a Mitchell and an Allen-Kingston competed. One of the S. P. O. cars, which was in the lead at the time, was disqualified for crowding the Hupmobile at the turns. The summaries follow:

One Hour Scratch Motor Cycle Race—Won by Indian (Walter Gorke); distance, 55¼ miles. Six Hour Race, Open to Stock Cars Costing \$2,500 or Less—Won by Hupmobile (Fred Woltmann); distance, 226 miles.

Five Mile Free for All—Won by Fiat Cyclone (De Palma); time, 5:14,3.5.

### Anti-Racing Movement Launched.

Lieutenant Governor Frank J. Hall, of Indiana, is reported to favor a special session of the Legislature to prohibit auto racing in the State. He is quoted as saying:

"They talk about bull fights in Mexico, but did you ever hear of several people being killed at a bull fight, and yet right here in Indiana great crowds go out to witness an event in which it may be expected that human life may be sacrificed. The Governor would be justified in calling a special session of the Legislature to pass a law prohibiting automobile racing under conditions similar to those of last week."

The Cincinnati A. C. has adopted resolutions condemning the recent automobile races at Indianapolis as hazardous and detrimental to the automobile movement. The resolution was adopted unanimously at a special meeting held August 26. It was also announced that it was the sense of the meeting that all members refrain from entering races, especially those similar to the Indianapolis event. The members present went on record as opposed to such races and agreed not to participate in them. Copies of the resolution adopted will be sent to all automobile clubs in the country, and their support of the movement thus started will be solicited.

It is reported from Dayton, Ohio, that the Dayton Motor Car Company have come to the conclusion that automobile racing is detrimental to the commercial interests of the industry, and the company will no longer participate in races. This conclusion was reached as a result of the fatalities at the recent Indianapolis race meet, which was attended by many employees of the firm.

### Sounding Makers Regarding Vanderbilt Cup Race.

H. E. Coffin, chairman of the general rules committee of the Manufacturers' Contest Association, has notified the prominent makers of the country that a race for the Vanderbilt Cup will be held late in October if a certain number of entries are pledged on or before September 1. If the makers guarantee the minimum number of entries required the race will be conducted by a new association formed pursuant to the A. C. A.-A. A. A. peace agreement, which association will assume the custody of both the Vanderbilt Cup and the Grand Prize Cup. By a change in the deed of gift the Vanderbilt Cup will become one for stock chassis competition under piston displacement classifications recommended by the Manufacturers' Contest Association, as follows:

I. The Vanderbilt Cup Race shall be open to cars of Sub-Classes I (45I to 600 cubic inches piston displacement) and 2 (30I to 450 cubic inches piston displacement) in

Class B, under the classifications of the A. A. A. racing rules for 1909.

2. A cup will be offered for Class 3 (231 to 300 cubic inches piston displacement), and another for Class 4 (161 to 230 cubic inches piston displacement) under the same classifications, these races to be run at the same time and on the same course, but for shorter distances.

If the Vanderbilt Race is held it will be run over the part of the Long Island Motor Parkway used in the cup event of 1908, with probably the same county and town roads. The race, if held, will be under the sanction of the A. A. A.

# Motor Cups Holding Company Formed.

Pursuant to the peace agreement between the A. C. A. and A. A. A. reached about a year ago the Motor Cups Holding Company of New York has been organized to promote automobile races for the silver cup donated by William K. Vanderbilt, Jr., and the gold cup donated by the Automobile Club of America, and known as the Grand Prize Cup. The company was incorporated on August 30, with a capital of \$5,000. The incorporators are William K. Vanderbilt, Ir., Henry Sanderson, Colgate Hoyt, Harry Payne Whitney, Harry B. Anderson, Elbert H. Gary, William Pierson Hamilton, H. B. Hollins, Dave Hennen Morris and Mortimer L. Schiff. Both events may possibly be held this fall. The Grand Prize race will probably be held again at Savannah, Ga., as the Savannah A. C. is negotiating for it, while the Vanderbilt Cup race may be held on the Long Island Motor Parkway.

Jackson Company Claim W. & S. Trophy.

The Jackson Automobile Company have made a formal claim to the American Automobile Association for the possession of the \$10,000 Wheeler-Schebler Trophy, which was offered as a prize in a 300 mile race at Indianapolis, Ind., which was called off in the 235th mile on account of various accidents. A Jackson car was in the lead at the time the race was called off. The A. A. A. officials state that according to its rules when a race is not completed there is no winner. The referee at the meet made a ruling of "no race" and will probably be sustained by the contest committee.

Ohio 1910 Number Tags.

The State Automobile Department of Ohio will take steps next year toward a better enforcement of the State automobile law. To that end a large number of facsimiles of the 1910 tag will be distributed to all peace officers in order that the genuine tag may be more quickly identified. The 1910 tag will be of heavy sheet iron especially prepared to withstand the wear and tear, and painted with a mahogany color. In addition to the serial number the tag will contain the word "Ohio" at one end and "1910" at the other end.

Metz Manufacturing Company Incorporated.

The Metz Manufacturing Company has been incorporated under Massachusetts laws at Waltham, Mass., to take over the business of the C. H. Metz Company, which nearly a year ago bought out the Waltham Manufacturing Company. The new company is capitalized at \$500,000. The directors are: John C. Robbins, president; Charles Spiegelberg, treasurer, and Charles H. Wolfe. Mr. Metz is the majority stock-holder. The company will continue to manufacture assembled parts for a runabout, which are sold under what is known as the Metz plan, the purchasers doing the final assembling themselves. It is said that nearly 200 men are at present at work in the company's plant. There has been some talk of removing the business to some other city, but the Waltham Business Men's Association has taken the matter up, and will make endeavors to hold the company.

Massachusetts Dealer's License Suspended.

The Massachusetts State Highway Commission has suspended the operator's license of Arthur L. Wilson, of Greenfield, a dealer in automobiles, for having in his employ the last six months unlicensed persons and allowing them to operate automobiles, and for failing to keep a proper record of the automobiles entering and leaving his garage or place of business.

### Anti-Dust Treatment of Milwaukee Streets.

The use of asphaltoilene as a dust layer has proven satisfactory in Milwaukee, and the city has bought an entire tank car from the Standard Oil Company, and has established a small storage plant at Riverside Park. Learning from a motoring trip in Illinois how successful the oil product was in abating the dust nuisance, automobile owners along Terrace avenue sprinkled that street at their own expense. As it proved very satisfactory there, the city ordered the sprinkling of other roads on which there is much automobile traffic, and the Board of Public Works then decided to treat all parkways with the preparation this year.

The mixture consists of asphalt and oil, and is said to preserve the crowning of the street by absorbing all dust wearing off of the macadam, as well as waterproofing the road and thus preventing injury by water. Water sprinklers are unnecessary where a road has been treated with the preparation. The cost is said to approximate 7 cents a square yard.

### Reduced Rates to Atlanta Show.

The Southeastern Passenger Association at a recent meeting in Chicago agreed upon a rate of fare of three cents per mile, one way distance, for the round trip to the Atlanta automobile show, to be held in November. This rate will apply not only in the territory of the Southeastern Passenger Association but probably to other terri-

tories in the East and West. The selling date and final limits for tickets for the auto show and races were left to a committee of Atlanta railroad lines.

#### Ohio Registrations.

According to the report of Fred H. Caley, Ohio State Registrar of Automobiles, the total revenue of the automobile department for the month ending August 15 was \$14,617.50. The revenue for the quarter ending at the same time was \$50,877: which is more than one-half of the total revenue derived from the automobile tax during the first year of the department's existence. More than 21,000 cars have been registered in Ohio to date, and it is believed that there are more automobiles in the State than in any other State with the exception of New York.

During the past month 1,340 owners registered cars, at a cost of \$6,569. There were also registered 424 chauffeurs, at a cost of \$848, and ten dealers, at a cost of \$100. Renewal papers were filed by 1,409 owners of cars and 24 manufacturers. During the quarter which ended August 15 there were registered 5,231 owners, at a cost of \$25,582, and 1,222 chauffeurs, at a cost of \$2,444. Dealers and manufacturers' licenses were issued to the number of 69, at a cost of \$690. Renewal papers were filed during the quarter by 4,249 owners and 10 dealers.

#### Must Keep Away from Hydrants.

Obstructing the work of the fire department by leaving motor cars standing on the curb within 5 feet of any fire hydrant has been made a misdemeanor by the city council of Los Angeles and, after a week of warnings only, the police are enforcing the new ordinance. In several instances automobiles were backed dead against fire hydrants, forcing the firemen to move the car before they could attach their hose and turn on the stream, thus causing loss of valuable time.

### Parry Automobile Company's Plans.

In announcing its plans the Parry Automobile Company, organized on July 28 at Indianapolis, states it will manufacture 5,000 cars during 1910, the first deliveries for the season to be made the 1st of October. Two models, a runabout and a touring car, both equipped with a four cylinder, 30 horse power engine, will be manufactured. The company has its new plant in the buildings formerly occupied by the Standard Wheel Company in operation.

# Want Tincher Company Sale Annulled.

A petition to set aside the sale of the Tincher Motor Car Company plant at South Bend, Ind., has been filed in the Superior Court by Charles L. and William C. Rayfield, stockholders. The Rayfields ask that the owners be restrained from distributing the assets, alleging that they

were prevailed upon to sign, unknowingly, an agreement to dispose of the company's plant. They say that they were led to believe that their signatures were necessary to make the sale of stock possible.

Demand for Second Hand Cars in Indianapolis.

Automobile dealers in Indianapolis report an unusual demand for second hand cars and a majority of the dealers have only one or two such cars in stock. The demand is said to be due to the fact that many dealers have sold their 1909 allotments and will not have any more cars for several weeks. Rather than wait indefinitely for cars, purchasers are taking second hand cars. Last year there was very little demand for such automobiles.

### Injunction Applied for to Prevent Lowell Races.

On Tuesday a young man was killed on the Lowell race course by Joe Matson, a driver, who was practicing for the race.

The same day Mrs. O. A. Gray, a property owner, whose lands front on 'the course, petitioned the Equity Court in Boston for an injunction to prevent the race on the ground that the act of the Legislature sanctioning it is unconstitutional, and that it would damage her property.

It is further claimed in the petition that while the special act sanctions the race, it does not sanction the practice for it, which has been going on for two days past.

Judge Dana, of the Superior Court, issued an order of notice on the Lowell Automobile Club, returnable at 10 a. m. Thursday, at which time his decision will be rendered.

### Speeder Banished from New York.

Felix Droit, a chauffeur, who had twice before been convicted of speeding, and the last time was sentenced to thirty days in jail and a fine of \$250, was again charged with the same offense before Judge Zeller in Special Sessions, New York, last week. The judge suspended sentence on the promise of Droit that he would never drive an automobile in the State of New York again. Droit, who has taken part in several races, including one Vanderbilt Cup race, was convicted of having driven at 20 miles per hour on Fifth avenue, between Ninth and Eleventh streets, on August 19.

### General Motors Stock Entered on New York Curb Market.

Both the common and the preferred stock of the General Motors Company have been entered on the New York curb market, and the first sale of common stock was made on August 31, at 155. The par value of both shares is \$100. It is stated that of the total of \$5,500,000 common stock authorized, \$2,724,580 has been issued, and of the \$7,000,000 preferred stock authorized, \$4,797,893 has been issued. The latter shares bear 7 per cent. interest, payable semi-annually, April 1 and October 1.

### MINOR MENTION

The Atlanta Automobile Association, which is building a race track at a reputed cost of \$300,000, has set the date of the inaugural meeting for November 9 to 13.

The Chansler & Lyon Motor Supply Company are now located at 916 East Pike street, Seattle, Wash. The firm's new home is well fitted. W. A. Avery is the manager.

J. G. Hatch and C. M. Dodd have opened a supply store at 914 East Pike street, Seattle, Wash., handling the goods of the Moore Motor Supply Company, of San Francisco.

The American Distributing Company has moved its headquarters from Cleveland, Ohio, to Jackson, Mich., so as to get in closer touch with the factories in the latter city which it represents.

The Long Distance Telephone Manufacturing Company, of South Bend, Ind., have secured a \$200,000 contract for automobile change gears, which are to be delivered within the next nine months.

The Badger State Tanning Company, of Sheboygan, Wis., has organized a department for manufacturing carriage leathers, and hopes to supply automobile manufacturers with the new product in the future.

Wm. L. Howard, of Trenton, N. J., has recently obtained two patents on a demountable rim which he intends to place on the market. Mr. Howard is manager of the Howard Cycle Company, 152 North Board street, Trenton.

The partnership between Joseph W. Owen and Eldie P. Wood, under the firm name of Owen & Wood, Los Angeles, Cal., has been dissolved, and the automobile and taxicab livery business conducted by the firm will be continued by Mr. Owen.

The Quaker City Automobile Club have decided to ask for the services of the State Fencibles for guarding the course in Fairmount Park on which their 300 mile race will be run October 9. The assignment of 400 soldiers will be asked for.

It is reported that the factory in Jackson, Mich., formerly occupied by the Buick Motor Company and which has been entirely reconstructed during the past two months, will be used for manufacturing trucks by the General Motors Company.

An unusually large shipment of automobiles recently went over the Lake Shore Road from Detroit to Chicago, and thence over the Chicago & Northwestern to Minneapolis, where the train was broken up. It contained forty-two cars loaded with several hundred Ford automobiles.

John O. King, inventor of the leather automobile tire, has brought suit against Lucius J. Elliott, a former partner, for \$30,000, which he claims he lost through "liott dissolving partnership with him, and

together with another man manufacturing the tire invented by King, patents on which were at that time pending.

The Moreland automobile factory may be located in Long Beach, Cal., if certain conditions of the promoters are met. Jotham Bixby, "father of Long Beach," is reported to be willing to donate a site of from 2 to 5 acres for the plant.

With the object of manufacturing an automobile cleaner, the Aquilla Chemical Company has been organized at Milwaukee, Wis. The new company is capitalized at \$5,000, with V. W. Alexander, W. A. Alexander and Frank C. Schoenherr as incorporators.

It is reported in Detroit that John G. Utz, formerly with the Chalmers-Detroit Motor Company, is organizing a company to manufacture a large car, and that another runabout is being developed by a local machine shop firm, which is said to be backed by General Motors capital.

The Kansas City branch of the Ajax-Grieb Rubber Company will move to new and larger quarters at 1606 Grand avenue some time the coming fall. This location is right in the centre of Kansas City's automobile row. The branch is now located at 1422 Grand avenue.

The firm of Wilberding & Brandewiede, Cincinnati, Ohio, has recently been incorporated with a capital stock of \$10,000. The firm conducts an automobile repair shop at 108 West Court street, and makes a specialty of overhauling engines and changing air cooled to water cooled engines.

The Columbia Electric Company, of Knightstown, Ind., manufacturers of the Leader car, have been reorganized. Moses Vandenbark has sold his stock to Luther and Earl Frost, of Greenfield, Ind., and Lon Thomas, of Willow, Ind. The new owners plan to increase the capacity of the plant.

During the week ending August 21, 168 cars were registered in New Jersey, as compared with 107 the same week last year. The most numerously represented makes were as follows: Ford, 19; Cadillac, 13; Maxwell, 13; Buick, 12; Olds, 7; Autocar, 7; Locomobile, Pope lines and Packard. 6 each.

The United States Pump and Tank Company has recently been organized at St. Louis, Mo., to manufacture automobile parts. Following are the officers of the company; J. J. Behan, president and treasurer; J. Curtis Barcus, vice president and local manager, and Fred F. Davis, secretary and general manager.

The Maxwell-Briscoe Motor Company, Tarrytown, N. Y., have made arrangements for parking 500 cars at the Lowell automobile races, having secured a reservation on the Lowell boulevard, from where a splendid view of the races may be had. All owners of Maxwell cars will be offered space in this reservation free of charge.

The Falls Rubber Company, of Cuyahoga Falls, Ohio, will have their administrative office in Akron, Ohio. J. N. Weid has resigned from the company, and the

board of officers is now as follows: Dr. S. H. Sturgeon, president; W. G. Short, vice president; H. F. Siegrist, secretary and treasurer, and Wm. Sherbondy, superintendent

C. A. McKiearnan, of Carthage, Mo., has constructed an automobile, and is organizing a company for its manufacture among local capitalists. A report on the car by H. F. Borbein, of St. Louis, has been submitted to local investors, and a committee has been named to place \$50,000 worth of stock in the new company.

Among recent additions to the membership of the Detroit Wholesalers' Association are the Anderson Carriage Company, Everitt-Metzger-Flanders Company, Cadillac Motor Car Company, Hupp Motor Car Company, Ford Motor Company, Briscoe Manufacturing Company, Packard Motor Car Company, Chalmers-Detroit Motor Company and Regal Motor Car Company.

The Middletown Buggy Company, of Middletown, Ohio, are planning to manufacture motor delivery wagons in two sizes for the coming season, one a light delivery wagon for useful loads of from 1,000 to 1,200 pounds, and the other one a heavier car for loads of from 2,500 to 3,000 pounds. The two cars will be equipped with solid rubber tires of 2 inches and 2½ inches width, respectively.

#### The Premier Glidden Protest.

H. O. Smith, president of the Premier Motor Manufacturing Company, of Indianapolis, has issued the following statement:

"The Premier Company regrets the necessity of making a protest on a point which on the surface might seem so trivial, but a number of cars have proven so good that only small points of vantage could be found by the technical committee at the conclusion of the strenuous run as the basis for determining awards.

"However, this contest was run under certain rules, and the rules specified under 'Qualifications,' paragraph 5:

Cars shall at all times during the tour carry mufflers and guards, and be fully equipped as per manufacturers' catalogue specifications, except that tops and wind shields need not be carried.

"The two roadsters of the same make as the car which was awarded the Glidden Trophy, which carried their lamps attached in the same manner as provided on the touring car of that make, suffered in consequence on account of the bad roads, by one having a bent bracket and a badly crushed lamp and the other by having the receptacle in the rear to which the lamp and bracket is attached entirely dragged off.

"The failure to carry lamps was in itself a violation of the rules, and judging by the experience of the roadsters of this make, which carried the full equipment, it is fair to assume that the touring cars which did not carry this equipment the entire distance escaped at least as much damage as was done to these two roadsters, and a report of the penalties shows that the roadster of this make, No. 109, with a total of 10.2 points,

harged among other things for retool box, bracket and tail lamp, 3 for time; bracket, 1.2 points for matail light, 3.2 points for material; other cars in the contest were charged mps and brackets, and in addition one are cars were compelled during the tal examination to light their oil to show that they were in good gondition."

#### lore Combination Rumors.

reported that George B. Cox, a prompolitician of Cincinnati, Ohio, is ening to combine several Eastern autofactories. A representative of Cox st returned from a visit to one of the less named in connection with the deal.

#### Garage Notes.

. Wetmore has established a garage at Corrille, Is. He has the agency for Chalmers

Segerstrom Auto Co., agents for Ridercars in Minneapolis, have moved to 219 1 street. South.

Allen-Kingston Motor Car Co. has secured ear lease at \$7,200 per year on a property adway, New York.

I. Gulestian, Cambridge, Mass., has bought of ground near Harvard Bridge, on which erect a fireproof garage building. garage of Scott & Shannon, Rugby, N.

garage of Scott & Shannon, Rugby, N. was destroyed by fire recently, and damage 2 \$7,500 and \$10,000 was caused.

t. Waters & Son, who handle the Stevensin Minneapolis, Minn., have secured temquarters at 24 Eighth street South.

Hutchinson has purchased the Arlington, Arlington, Cal., from R. D. Woodward, Il move it back to its former location.

. Doyle, St. Cloud, Minn., will erect a two 100 feet square garage building, to cost 520,000. The location has not yet been deed upon.

ris & Reed, Sioux City, Ia., have bought out ntral Machine Works, whose plant they will t into a garage. They are general agents ack automobiles.

Georgia Automobile Exchange, Columbus, is increased its capital stock to \$25,000, and once erect a modern garage building with om and repair shop.

Odd Fellows Hall, on Broad and Spring streets, Philadelphia, has been purchased automobile company, which will erect a concrete garage on the site.

H. D. Ryus, who was formerly connected he White garage in Los Angeles, and rewas appointed agent there for the Corbin a opened a garage on Broadway.

C. Wilson and Fred Gumbert, who handle purist and Locomobile in Portland, Ore, noved into a new garage on Alder street, be-Sixteenth and Seventeenth streets. This of the largest garage buildings in the city, ing 160x70 feet.

Jones Automobile Exchange, of Wichita, will erect a \$30,000 garage as soon as the re completed. The building is to be 50x140 nd will have a pressed brick front. The part of the floor space will be occupied by ral agency of the Ford Co., which is con-

by Mr. Jones.

Phillips Automobile Co., St. Louis, Mo., ecured a permit from Mayor Kreismann to a garage in the alley east of Kings Highetween Page and Easton avenues. The ty some months ago applied for a permaranchise for the garage, but the application posed by residents in the district, and the denied it. The mayor now has granted mpany a ninety day permit so that they

may demonstrate that the garage can be conducted without being a public nuisance.

George Fuller, of Deadwood, S. Dak., has sold his garage to J. C. O'Donnell, Jr.

Joseph B. Dryer, St. Louis, Mo., is building a garage at 1521 North Grand avenue. He expects to secure the agency for a line of cars.

The Maxwell-Briscoe Automobile Co., Kansas City, Mo., has let the contract for a three story garage building at 1612-1614 Grand avenue.

The Studebaker Automobile Co., Louisville, Ky., are negotiating for the purchase of a property at Fourth and York streets, where they plan to establish a salesroom and garage.

The C. F. Bullwinkel Estate, district agent for the Studebaker and allied lines at Jefferson, Wis., now occupies its new garage, which includes large offices and a big supply department.

G. M. Irwin will open about September 1 the Uptown Garage, at 154, 156, 158 and 160 West 124th street, New York, with storage facilities for 300 cars. An agency will also be taken.

A. P. Hess, formerly of Montesano, Wash., has recently incorporated the Avenue Automobile Co. at corner Seventh and Pacific avenue, Tacoma, and will handle the Franklin cars during 1910.

W. C. Cook and Henry Allingham, San Diego, Cal., have bought the Union Garage from the Southern Electric Co. Cook was foreman of the garage for two years, while Allingham formerly conducted an automobile service.

The White Garage Corporation of Los Angeles, Cal., which was first organized several years ago, and reorganized about a year ago by Col. F. C. Fenner, has given up the agency for White cars, and will take on several other lines.

N. C. Bickle, of Chardon, Ohio, has leased the old unoccupied Chardon Baptist Church, which he will remodel into a garage. The church was built about seventy years ago, and was abandoned on account of the dwindling of the congregation.

The Woolwine Motor Car Co., Los Angeles,

The Woolwine Motor Car Co., Los Angeles, Cal., have let the contract for a single story pressed brick garage, 70x165 feet, on Olive street between Eleventh and Twelfth. The company will this year handle an extensive line of cars.

W. O. Houghton, Galva, Ill., has purchased a building site, and will immediately begin the construction of a single story garage building with a frontage of 30 feet and a depth of 60 feet. The building has already been leased to Hal Bailey.

Walter J. West, an automobile dealer of San José, Cal., disappeared on August 9, and no clue to his whereabouts can be found. He is said to have had no financial trouble, and it is thought that his disappearance may have been due to temporary insanity.

Frank C. De Water and Edwin De Water, of

Frank C. De Water and Edwin De Water, of Islen, N. J., have leased a property at 71 Prince street, Elizabeth, N. J., for one year beginning December 1. There are two buildings on the premises, which are to be used for live and dead storage respectively.

Milton Stiles, Ventura, Cal., will erect a two story garage building on the corner of Main and Palm street, instead of a single story building as formerly planned. The upper story will be fitted up for office rooms. The building will have a pressed brick front.

Long & Histed, who have recently taken the agency in Kansas City for American Simplex, Overland and Brush cars, are making extensive improvements to their salesrooms and garage at 1527 Grand avenue, including a hardwood polished floor in the salesroom.

Arthur E. Genereaux, of Cleveland, Ohio, has secured a half interest in the Central Garage on Union street, Pasadena, Cal., and will be manager of the garage in the future. Connected with the garage are the agencies for the Oldsmobile, Chalmers-Detroit and Hudson cars.

The Lucia Brothers Motor Car Co. is the new name of the well known Green Bay, Wis., agency and garage firm, which was established under the name of Lucia Cycle Co. in 1888. The company is probably the largest dealer in motor cars in Wisconsin, exclusive of Milwaukee, and besides its main garage at 218 and 220 North Adams street. Green Bay, has a large branch garage at

Oconto, and branch agencies in several other large cities in northeastern Wisconsin. The company represents the Chalmers-Detroit, Hudson and Thomas.

The Atlas Machine Co. has been organized in Louisville, Ky., with \$40,000 capital stock, to handle the Empire car, which was described in our last week's issue.

The newly established Pittsburg branch of the H. H. Franklin Manufacturing Co., of which W. F. Reynolds is manager, has secured headquarters at 5926 Baum street, of which it will take possession on September 1.

The Oxford Hardware Co., Oxford, Ohio, will erect a garage building on a lot recently purchased. It will be of L shape, 80 feet deep on one side, and 40 on the other. The company expect to handle several lines of automobiles.

The Banker Brothers Co., of Pittsburg, has been reorganized as the Pioneer Motor Car Co., with W. J. Lewis as the active head. The new company will take over the entire business of the old one, and will handle the Lozier, Hudson and Chalmers-Detroit cars.

Cuyler Lee, a prominent San Francisco dealer, has let the contract for the erection of a \$70,000 garage and salesroom on Jackson street and Van Ness avenue, on a site which was recently purchased for \$45,000. The building will be three stories high, 67x125 feet.

Pugh Brothers, who handle the Elmore, Overland and Autocar truck in Providence, R. L., will move into their new garage on Mathewson street on September I. The garage has storage capacity for seventy-five cars, and comprises a well equipped machine shop.

well equipped machine shop.

A sort of motor mart building is at present being erected at 223 Peachtree street, Atlanta, Ga. Space in the new building has already been let to Frank Steinhauer, who is at present conducting a garage in an old skating rink in the rear of the Aragon Hotel, and to J. E. Levi & Co., who represent the Reo.

Protheroe & McGinnis, of Baraboo, Wis., are building an addition to their garage on Third avenue. The building will be of solid brick, 44x90 feet, and will be used exclusively for storage and livery. The present building, 24x72 feet, will be used for exhibits, accessory department and repair shops,

A Baltimore automobile firm is negotiating for the purchase of the property at the east corner of Mt. Royal avenue and McMechen street, formerly used as a car barn by the United Railways. The property has a frontage of 202 feet, a depth of 165 feet, and is improved with a one story brick building well adapted for use as a garage.

The Shaw Auto Livery Co., of Chicago, has secured a building permit for a garage in Evanston avenue between Grace street and Waveland avenue. Objection was raised to the application by a property owner in the vicinity, who held that the block was a resident block, and that frontage consents were necessary. The Shaw Co. succeeded in obtaining the necessary signatures.

The H. O. Harrison Co., of San Francisco, agent for the Peerless car, is occupying a new brick and steel building, two stories high, in Mission style, on Van Ness avenue, near its junction with Golden Gate avenue. The front is devoted to offices and showroom, while in the rear a large stock of parts is kept. The repair room, on the second floor, is reached by a large elevator.

second floor, is reached by a large elevator.

A. J. Winters Co., Portland, Ore., have bought the stock, lease and fixtures of the Coleman Hardware Co., and are adding a stock of automobile supplies. They are at present installing a modern vulcanizing plant in the rear of an adjoining building. They plan to do a general wholesale business in shop tools and automobile supplies, and will issue a general tool and supply catalogue.

Bids have been asked for on a 50x126 feet single story garage building to be erected on Prospect street, Bellingham, Wash., by the Long Estate. The front will be of light cream pressed brick, and will have large plate glass windows. The floor will be of cement. There will be a 16x24 foot office and accessory room in the forward portion of the building, and a 26x50 feet repair shop in the rear.

#### Trade Personals.

Hobart M. Adams has resigned as manager of the local and State retail department of the White Co., Cleveland, Ohio, and has been succeeded by Frank E. Stiverson.

H. D. Penney, who was formerly connected with the Remington Arms Co., of Ilion, N. Y., has accepted the position of tool designer with the Toledo Motor Co., Toledo, Ohio.

L. G. Hupp has resigned as commercial agent of the New York Central lines in Grand Rapids. Mich., and on September 1 will accept a position with the Hupp Motor Co., of Detroit.

Nelson S. Gotshall, who was manager of the Studebaker and E-M-F sales branch in Minneapolis until recently, has become Western sales manager for the Simplex Motor Car Co., of Mishawaka. Ind.

S. B. Robertson has resigned as assistant manager of the Studebaker branch in Kansas City, and on September 1 will assume the management of the Buick branch in St. Louis, succeeding E. W. Nothstine.

H. A. Post, formerly of Buffalo and Denver has been appointed sales manager of the Falls Rubber Co., Cuyahoga Falls, Ohio. The com-pany, which was organized recently, will manufacture a line of automobile tires.

Paul L. Snutsel, foreign representative of C. F. Splitdorf, sailed Saturday, August 28, on the S. S. Zeeland for an extended trip to London, Paris, Turin, Barcelona and Brussels, in each of which cities Splitdorf branches have been established.

W. A. Webber, formerly manager of the New England agency for American cars in Boston, has recently assumed the position of sales manager for New England for Allen-Kingston cars, and will make his headquarters in Boston with Warren I. Jacobs, New England distributor for Allen-Kingston cars.

Arthur W. Haile has been appointed city sales manager for the E. R. Thomas Motor Co., of Buffale, N. Y., succeeding C. T. Paxon, whose appointment as manager of the Chicago Thomas branch was announced in our last issue. Haile was assistant city sales manager in Buffalo for the past three years.

O. L. Weaver, who for ten years was connected with the Goodyear Tire and Rubber Co., during the last six as manager of their Cincinnati branch, has severed his connection with that company to become factory sales agent for Over-land cars in eastern Ohio, western Pennsylvania and West Virginia, with headquarters in Cleve-

#### New Incorporations.

The Columbia Taxicab Co., St. Louis, Mo.-Capital stock, \$200,000.

Renault Frères Selling Branch, Chicago, Ill.-Capital stock, \$5,000. Incorporators, Wm. Burry, G. M. Peters and D. R. Eichberg.

The Coston Automobile Co., Asheville, N. C.-Capital stock, \$2,000. Incorporators, E. V. Reynolds, J. A. Coston and Junius Adams.

The Saurer Motor Truck Co., West Orange, N. J.—Capital stock, \$200,000. Incorporators, W. D. Sargent, West Orange; G. M. Judd and E. H. Fallows, New York city.

The Auto Tire and Repair Co., Cincinnati, Ohio. -Capital stock, \$10,000. Incorporators, Alexander Schwendler, Francis A. Hoover, R. D. Anderson, G. W. Ernest and Tillie M. Anderson.

Studebaker-Colorado Vehicle Co., Denver, Col. -Capital stock, \$100,000. Incorporators, Frank S. Fish, president; W. S. Hunnewell, vice president and treasurer, and Elias K. Pound, secre-

#### New Agencies.

NUMBER 10

### Novel Methods of Producing Gears.

By F. E. WATTS.

demand in the higher priced autos ore quiet operation on the lower has made necessary the production is with more perfect tooth forms, and same time the advent of low priced ith two and three speed sliding gears ade it imperatively necessary to proets of reasonably quiet gears at a

e somewhat conflicting conditions in tion with the two classes of cars aused makers to experiment with vanethods of forming the teeth of their ission gears. For the production of e gears, both spur and bevel, gear or planers which generate the teeth st commonly used. During the past r so, however, there have been a rable number of hobbing machines iced into the more prominent shops, e manufacture of spur gears. In nstances these machines are giving I satisfaction, lowering the cost of ars and at the same time apparently ing gears which are more uniform in least they run more quietly. In shops the hobbing machines are deinferior to the shapers, both in cost luction and in quality of the product. question of which method is best ot appear to be decided as yet from ical standpoint at least.

no matter how well the gears are ey will still make a little noise, so the greatest quietness is required they un in" or lapped together with an e powder. That is, the gears are ed in pairs, just as they mesh when e in the change gear, and run by with the teeth dipping in a bath of ed with emery powder or some simbstance. Sometimes the shafts of running in" fixtures are arranged so eir centre distances are adjustable, that these distances can be measured usandths of an inch by means of eter heads. The gears must then be urately enough so that they will lap in quietly with these centres a specistance apart, within given limits. If ers were used soft, just as they were is probable that if the work was first omparatively little lapping would be d. But sliding gears must always dened or case hardened, and these es always throw them a little out of So we must amend our former stateor the more important cause of noise is not inaccuracy in the cutting but warping while hardening.

The gears for the cheaper cars are not generally lapped in, but even these are nearly always "run in" in oil, after being assembled in their case, for some time before placing in the car. Bevel driving gears are practically always lapped on the better cars, and even on some of the cheaper machines. So common has this process become that fixtures for the purpose are now an article of manufacture.

Quite recently a process for grinding the teeth of gears after they are hardened has been developed. Each tooth is brought exactly to size, and it is claimed that the resulting gears are practically perfect. If this process works out commercially as well as it is said to have done experimentally, the present methods of running in gears will doubtless soon become obsolete.

In the search for methods of producing gears more cheaply for parts other than the transmission system, where the gears usually do not require to be as perfect and often do not need to be made of exceptionally strong material, many ingenious methods are being tried.

Die cast gears of certain of the special die casting alloys are being tried with considerable success. They appear to be strong enough to use for driving magnetos, pumps and similar parts, and can be made quite accurate.

For bevel differentials drop forgings used rough are perhaps among the possibilities, though I do not know that they have yet been tried. Differential gears cast from some of the new cast steels are certainly practical.

Some small internal gears are being satisfactorily made by broaching. Whether a similar process can be satisfactorily used for external gears or not is a question. There would seem to be difficulties in the way of keeping the dies sharp and to size, and those tool makers with whom I have talked regarding the matter do not think the process practical.

The hot rolling of spur gears is being experimented with, but I do not know that any successful results have been attained.

For cutting spiral gears thread millers are being used where the pitch is not too great with relation to the diameter. But where the teeth run nearly axially the hobbing machines seem to be the favorite tools. Certain shapes of these gears can be pro-

duced very cheaply and they are coming more and more into favor for small work, since they are quiet and reasonably efficient.

Regular worms and worm wheels must, of course, be hobbed, but these are not used to a sufficient extent, except for steering gears, to induce the development of special methods for their manufacture.

Special forms of gears, such as pin gears, face gears, etc., are being tried for some of the cheaper cars, and it is by no means certain that some of them may not possess merit. Face gears, or more properly "crown" gears, have been tested and show an efficiency of slightly more than 90 per cent. when transmitting small powers. The pin gear transmissions may be made rather rugged, since the spur gears which mesh with the pin teeth have rather coarse pitch and comparatively narrow faces. It is probable that they can be cut quite cheaply in gangs, since very heavy cutters can be used for roughing out. It is also not unlikely that the teeth can be cast nearly or quite to size, for this has been done on teeth of similar shape used in high powered cars with rather satisfactory results both as to cost of production and quietness of operation. In the pin gears themselves, the teeth being perfectly round can, of course, be made very rapidly. Their sockets may be rapidly produced by multiple drilling and reaming. The teeth may be inserted by a magazine feed automatic machine, and the heading which secures them in their sockets is done by a spinning tool. It should be understood, of course, that the working ends of these teeth are hardened while their shanks are left soft.

All in all I think we are justified in saying that change gear design is by no means settled, and that the present activity in this direction is likely to produce some useful results.

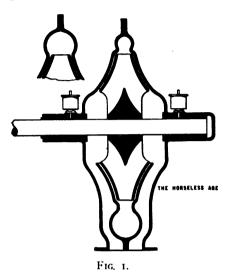

### Imports at the Port of New York.

During the month of August there were imported at the Port of New York by dealers, 80 pleasure cars, 69 taxicabs and 8 trucks, and by individuals 45 old and 11 new cars. Among the pleasure cars imported, Renaults lead with 28, followed by Fiat with 25, Mercedes with 8, Isotta with 5, etc. Of the taxicabs 49 were De Dion-Bouton and 12 Fiats. The total number of cars imported during the month was 213, and they were valued at \$478,202.66, as compared with 216 cars valued at \$431,829.43 imported in August, 1908. It will be noticed that taxicabs now form a very considerable portion of the imports.

### Construction of Centrifugal Pumps for Automobiles.

BY EUGENE P. BATZELL

Centrifugal pumps are used more and more in connection with gasoline automobile motors for circulating the cooling water. Almost every concern manufacturing its own motors manufactures also the

centrifugal pumps for them. This is the reason why there are many different types of such pumps, and not one is considered standard. But among all of these constructions can be found only a few which are really correct from the theoretical as well as from the practical standpoint.

It is true that the centrifugal pump used for an automobile motor serves only as an accessory, and may be regarded as of minor importance. Besides, if a centrifugal pump is put out of action, and all its pipe connections remain, the cooling action continues on a reduced scale, owing to thermo-siphon circulation of the water. It may also be urged that centrifugal pumps consume only little power, and their efficiency is, therefore, of no great importance. However, it is possible in each case to make a pump both theoretically and practically correct in construction by simply paying a little more attention to its design. Many centrifugal pumps actually found on automobile motors convey the impression that they were fitted to the motor more for the purpose of suiting the taste of purchasers than for anything else.

There are some designs of centrifugal pumps which, while entirely correct theoretically, are too complicated, and, therefore, too expensive to manufacture. In general, some of the types of pumps which have proven very advantageous for large stationary plants are of no particular advantage for automobile work.

It is always advisable to consider the cost of manufacture and design the pump accordingly. The price of the motor and its intended use should always be taken into account. For racing car pumps, where the cost is a small consideration, it is advisable

use a more complicated and expensive

ordinary pleasure cars the pumps must be built simpler and cheaper, however.

The general form and the dimensions of the pump parts must be made in accordance with the conditions under which the pump is

construction if the reliability can be in-

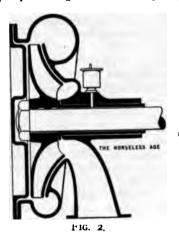

creased thereby. It is better in this case

to forestall all possibility of defect. For

the pump parts must be made in accordance with the conditions under which the pump is to operate. The most important problem is that in relation to the form of the blades for the pump wheel and the dimensions of this wheel. This problem will be discussed in detail further on.

Several forms of centrifugal pumps are shown in Figs. 1, 2 and 3. The arrangement Fig. 1 is largely used in stationary pumps, but is not particularly suited for automobile motors. It necessitates the use of complicated and expensive castings. The friction surface between the water and the passage walls is great, as the passages are divided into two, each of small area. When the wheel is cast the inside surface of the passage walls generally comes out very uneven, as the size of these passages is small, consequently friction losses are further increased and the effective cross sectional area is reduced.

This arrangement necessitates splitting the pump housing in a central plane, as

shown. Such a joint is generally very undesirable. It is hard to keep the joint tight when the flanges are not large and the joint screws are not big enough. It is generally impossible to have both the flanges and the screws of the proper size, as the outside dimensions of a centrifugal pump for an automobile motor are nearly always limited by the small space between the bonnet and the crank case. If a part of this space were were to be occupied by a large flange the pump wheel would have to be made proportionately smaller, and this would decrease both the pressure and the delivery of the pump.

One other reason why a joint in the central plane of a pump is hard to keep tight is that this plane lies parallel with the direction of the water passing through the diffuser. The water tends to penetrate

through the joint directly, and this effect is increased by centrifugal action.

The one advantage of this construction, viz., complete absence of thrust on the pump shaft, is of no great importance in the case of automobile pumps, as there the thrust is very small. Besides, it is necessary, anyhow, to provide thrust bearings for both directions, so that the wheel with its shaft may not be thrown out of position by the vibration of the automobile.

The arrangement Fig. I could in any case be advantageous only in pumps of large size for big motors, where it is desired to circulate great quantities of water. But in ordinary cases, even for racing cars, simpler constructions, like those shown in Figs. 2 and 3, would be preferred.

Fig. 2 shows a pump comprising a wheel with completely enclosed water passages. Fig. 3 shows a pump with water pasages open on one side. This last construction is the cheapest, because the wheel can be cast without cores. But theoretically it possesses some disadvantages. Owing to the difference in pressure at the entrance and exit of the wheel passages there is always a back flow of water through the cheeks, between the wheel and the housing. In the pump Fig. 2 this back flow of water is separated by walls from the main flow through the wheel passages. In the pump Fig. 3 these two flows are in direct contact and form eddy currents, which decrease the efficiency of the pump. These extra losses are reduced, however, by the fact that while in construction Fig. 2 the inside walls of the wheel passages cannot be smoothed, and must remain as rough as the casting is made, in the construction of Fig. 3 these walls can easily be considerably smoothed, even when the casting is only cleaned by a sand blast.

Another difference between constructions 2 and 3 relates to methods of machining. The outside of the wheel in Fig. 2 can easily be roughly finished, which is all the finish required. It is harder to finish the wheel in Fig. 3 to the correct shape on the side where the blades are open.

Where cost of construction is a very important item it is advisable to follow the design Fig. 3. The wheel passages must be made larger; that is, of greater area than

Fig. 3.

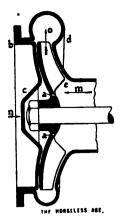

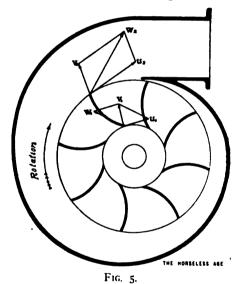

Fig. 4.

is required theoretically for the quantity of water to be circulated in a given time, owing to the back flow already referred to. It is, of course, advisable in any case to make the passages rather large, so as to keep down the velocity of the water from 8 to 10 feet per second for the maximum discharge.

In pumps Figs. 2 and 3 there is a certain end thrust on the pump shaft, as the lateral surfaces of the wheel at the right and left

side from its passages are not equal. It will be seen from Fig. 4 that the area of the side ed is smaller than that of bc. As the water pressure per square inch on both these surfaces is the same, there will be a thrust on the pump shaft in the direction indicated by the arrow n. This thrust may be decreased by drilling a few small holes a close to the beginning of the blades. This thrust is slightly decreased by the reaction due to the change in directions of the water flow in the wheel from n to a.

Thrust in the direction opposite to arrow n occurs in pumps Figs. 2 and 3 at the moment of starting. There is then no pressure on the sides e d and b c, but the reaction due to the change in directions of the water is present. Thrust bearings for taking up the thrust in both directions are therefore necessary for pumps Figs. 2 and 3.

An advantage of pumps Figs. 2 and 3

over pump Fig. 1 consists in the simpler pump housing. Also the joint between the two valves can be located to one side of the largest diameter of the diffuser, so the flange will not increase the over-all dimensions, and the whole pump can be made larger. It is also easier to keep this kind of a joint tight, as the water coming out of the wheel flows in a direction perpendicular to the plane of the joint.

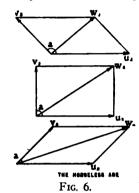

The pump Fig. 1 usually has two bearings for the pump shaft, one at each side of the wheel. In the pumps Figs. 2 and 3 it is preferable to use only one long bearing, if the shaft does not need to be carried out of the housing for some purpose. With a long single bearing on the shaft it is possible to do without a stuffing box, provided the bearing is located on the suction side of the wheel. If the bearing is located on the other side of the wheel, where the pressure is theoretically almost equal to that in the diffuser, it is better to use a stuffing box, particularly if the bearing is not made very accurately. This last construction, with a single bearing located on the pressure side of the pump, allows of a simpler arrangement for conducting the water to the wheel (Fig. 3). When the bearing is located on the suction side of the wheel the pump intake becomes more complicated, as the incoming water surrounds the pump shaft (Fig. 2).

Aside from the construction of the wheel the diffuser also plays a very important part in a centrifugal pump. This part, by which the water, after leaving the wheel, is directed to the pump outlet, is most correctly made of spiral form (Fig. 5). The largest section of the spiral is known, being equal to the pump outlet opening. A few more sections are calculated, they being proportional to their distance from the beginning of the spiral, and then the whole passage can be drawn.

If it is desired to keep the losses in the pump low then that portion where the water leaves the wheel and enters the diffuser may be laid out, as shown in Fig. 1, at a. Here the housing extends beyond the side

walls of the wheel, and there is no sudden change in the area of the water passage. But ordinarily the construction shown at b, Fig. 1, or that of Fig. 3, would serve the purpose.

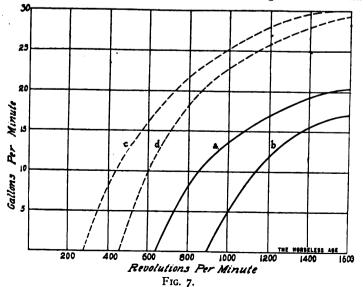

The diffuser serves the purpose of converting the high speed, low pressure flow of water into a low speed flow of higher pressure. For instance, if the water leaves the wheel with velocity  $v_2$  (Fig. 6), and if the peripheral speed of the wheel is u, the absolute velocity of the water is equal to the

resultant of  $v_2$  and u, which is represented by  $w_2$ . A part of the velocity  $w_2$  can be transferred into pressure in the diffuser. If the water leaves the diffuser with a velocity v, then the increase in pressure in the diffuser is proportional to  $w_2^2 - v_2^3$ .

If the velocity  $v_2$  is constant, then  $w_2$  depends upon the velocity u2 of the wheel, and also on the angle between the outer portion of the wheel blade and the wheel circumference. as the velocity v2 is always in the direction of the outer end of the blade. Fig. 6 showshow we changes when the angle a of the blades is changed, but both velocities v2 and u2 remain constant. It shows that when the angle between the velocities v2 and u is decreased, and therefore the pump is able to work at higher pressure, then velocity wa is increased. It is therefore possible to use the same pump for both low and high pressure, by simply arranging the form of the blades accordingly.

In determining the form of blades for a

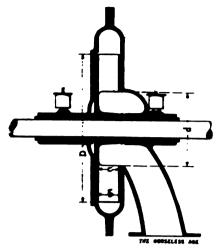

FIG. 8.—FAULTY CONSTRUCTION.

pump it is necessary to consider that the radiator may sometimes not be full of water; whether the motor will often have to deliver much power at low speed, and at what speed the motor will be run the most.

Very often the pump is driven at the same speed as the magneto. For six cylinder motors this is equal to one and one-half times crank shaft speed, and for four cylinder motors equal to crank shaft speed. The same pump could then be used for six cylinder motors as for four cylinder ones, only the blades of the wheel would have to be more inclined backward. But if the six cylinder motor is run much at low speed (at which it is able to develop much more power than the four cylinder), then it would be advisable to use the same pump as a four cylinder motor of equal power rating.

In Fig. 7 are shown some curves representing the discharge of a pump as a function of its revolutions per minute. Curve A is of a pump in which the rotor blades were inclined back from the direction of rotation. Pumps with blades inclined backward should be used only on racing cars. The inner end of the blades must always be inclined in the direction of rotation of the wheel, so as to make an angle of 50 to 70 degrees with the radial line (Fig. 5).

In conclusion may be shown a number of faulty designs of centrifugal pumps, and attention called to the faulty points.

Fig. 8 shows a construction in which the width of the water passages of the wheel is the same at the outlet b and the intake c. It would be more correct to so design the

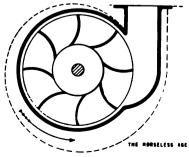

Fig. 9.—Faulty Construction.

passage that the velocity of the water through the wheel passages would be nearly constant. This necessitates a tapered wheel, the width decreasing toward the outlet so as to make  $d \times c = D \cdot b$ . If there is back flow through the passages, dimension b must be made larger than it should be according to this formula.

Fig. 9 shows an incorrectly designed diffuser which extends only over a part of the circumference of the wheel. Only that part of the wheel opposite the diffuser at a certain moment can deliver water, and this pump gives much less water than it could give if the diffuser were made correctly; that is, if it surrounded the whole wheel, as indicated by the dotted line. Owing to the fact that in the rotation of the wheel the part from which water is delivered is constantly changing, a certain amount of power is lost through the inertia of the water which is locked up in the wheel passages not under the diffuser. Theoretically such a pump should give a periodical delivery of water, although the periodicity would be

Fig. 10 shows a design of pump in which the pump wheel extends out into the dif-

FIG. 10.—FAULTY CONSTRUCTION.

fuser. Generally the water flows through the diffuser at a comparatively slow speed, and in high speed pumps this velocity is much less than the velocity of the rim of the wheel. Therefore, the part of the wheel which extends into the diffuser and passes through the water therein with high speed will strongly churn the latter. Correct operation of such a pump is out of the question—it will deliver only a very small quantity of water and consume much power.

The construction of Fig. 10 was probably due to a desire to make the wheel of large diameter and still keep down the outside dimension of the pump. But much better results would be obtained in this respect with a construction similar to Fig. 2, which is used by the author. Here the outside of the wheel comes close up to the diffuser, as ordinarily, but the diffuser is placed over to one side of the wheel. This arrangement insures an easy flow for the water coming out of the wheel, as the passage is bounded on one side by the housing itself.

Fig. 11 also shows an incorrect diffuser, which is not spiral cut concentric with the

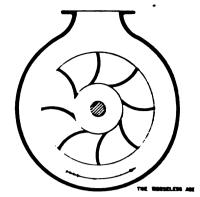

FIG. 11.—FAULTY CONSTRUCTION.

wheel. It is claimed that this construction can be made easier and cheaper, but that is of doubtful advantage here. The passage in this diffuser does not have the form required by the theoretical flow of water, and this involves great loses.

#### A Waste Product as a Dust Layer.

It has recently been reported in sundry newspapers that wood pulp is being used in the making of good roads, and that it has been used with good effect. Inasmuch as wood pulp costs \$18 to \$20 a ton, its use would prove excessively expensive. What is really used is the waste liquor from the sulphite digesters in use wherever paper is made from wood.

For many years the disposal of sulphite liquor has caused much trouble to paper makers. When this substance has been dumped into rivers all kinds of trouble have arisen, in which boards of health and law courts have figured prominently. The liquor contains a percentage of rosin and pitch, cooked in the sulphite digesters from the spruce wood mainly used in the manufacture of wood paper, and this, after being applied to the roads, hardens, forming a binder dressing that will, it is believed, last for months and prevent the dust from blowing from the road.

Experiments in this direction are now being conducted by the officers of the St. Regis Paper Company, one of the largest paper making concerns in the State of New York. These experiments are to determine the adaptability of the waste liquor, as paper makers usually term it, for road making purposes. The liquor is being sprinkled on the roads in the vicinity of De Feriet, N. Y., it being thought such application will solve the dust problem, which, since the advent of the automobile, is more serious than ever. If successful these experiments will turn the waste liquor into a revenue producer, which the officials in question heartily desire may be the case.

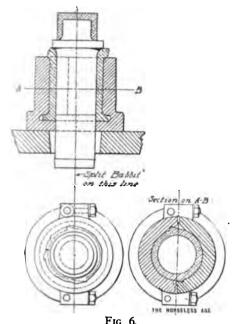

In addition to the experiments at De Feriet the St. Regis Paper Company recently shipped five barrels of the liquor to another part of the State, where it is being tried. The results at De Feriet, while perhaps a little premature, seem to indicate that the top dressing will prove all that is hoped.

### Babbitt Bearings—II.

By S. M. UDALE.

VII. - MACHINING THE BEARINGS.

The babbitt should be cast in cylinders three-eighth inch thick, with an internal diameter three-one-hundredths inch small. In order that the alloy may be consolidated,

of the

and the roots of the keys defined and driven into the main body, these cylinders are placed in a die and a tapered and a straight mandril are driven down successively, leaving the bearing (Fig. 6) from one-one-thousandth to three-one-thousandths inch under size. The bearings are then split by a one-thirty-second inch saw, allowing for which subsequently requires thirty-three-one-thousandths inch in shims between the boxes.

The main bearings are best reamed in place. The keys for the upper halves of these bearings are best trimmed down somewhat, so that they can be rolled out without taking the crank shaft down. The oil holes are usually in the top, fed by a pressure oiler.

The upper crank case should be placed on a horizontal boring machine and a long reamer run through, so that the crank shaft may be exactly true with the axes of the cylinders. The final cut of the reamer should leave the bearing one-one-thousandth of an inch large. To give the proper side c'earance the cap bolts are loosened up and the right distance pieces are placed between the caps. The reamer to cut this clearance is then placed in, and the bolt tightened up so that the reamer just cuts. As the cap is bolted down gradually onto the distance pieces, the table of the machine must be gradually raised. The reamer should revolve in the direction of rotation of the crank shaft (Fig. 7).

The calculations for the size of the clearance reamer and the distance piece are given in the appendix (Fig. 8), together with a discussion by Goodman ("Mechanics for Engineers") on the value of side relief to bearings.

The connecting rod bearings are placed in position, and the connecting rod is securely bolted to the jig shown in Fig. 9, which latter is bolted to the table of a drill press. Reamers are then sent through until the bearings are exactly one-two-thousandths inch over size. The jig is then moved a distance equal to half the thickness of the liners used, to get the requisite clearance (Fig. 7) away from the axis of the drill spindle. Reamers (increasing in size) are then put through until the required side clearance is obtained.

To complete the bearings, and incidentally to test them, they should be spun after the engine is assembled at 700 r. p. m. for three hours, with clean oil in the crank case and the cooling water circulating in the jacket. The spinning should precede the actual engine test, and should be made without gasoline. By having the throttle closed less power is used up and less noise is heard than if the exhaust is into the air. This three hours' driven run will shorten the time that is necessary to properly test the engine, and incidentally eliminate much serious trouble by giving timely warning.

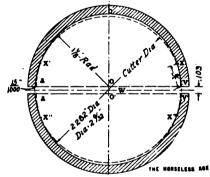

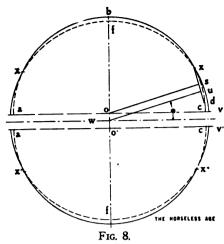

FIG. 7.—SIDE CLEARANCE.

VIII.—LUBRICATION AND OIL GROOVES.

The usual system of oiling the babbitt bearings is to feed the main bearings by a mechanically operated standard pressure

oiler. The oil from these bearings drains down into the lower crank case, where the rapidly revolving crank bearing carries it up to the cylinder walls and to the wrist pin. The oil then drains down the connecting rod and enters the connecting rod bearing by four holes, two-on either side of the web. The result of this method (or lack of method) of oiling the crank bearings is that three times as many knocks are heard from and about connecting rod bearings as about main bearings. In Fig. 9 an arrangement is shown whereby oil is picked up and driven up into the space above the bearing, which device can easily be boxed in with a thin metal cover riveted in between the flanges of the connecting rod. With two holes there would be two reservoirs of oil, but by connecting them together additional security is gained.

The oil grooves in the main bearing should be in the upper half and near the middle. Little or no pressure comes on the upper halves, and the head of oil will always carry it in. The connecting rod bearings should also have an oil groove in the upper half, but low down in the clearance zone. This groove should be on the "on" side, as it has been experimentally shown that the oil is thicker here and the pressure least. As the head of oil available, even with the somewhat elaborate device shown

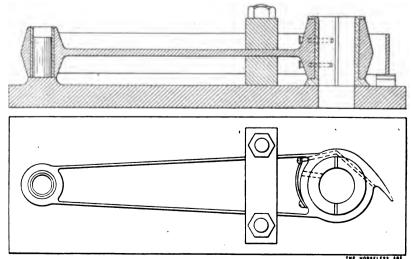

Fig. 9.—Jig for Machining Connecting Rod Big End Bearings.

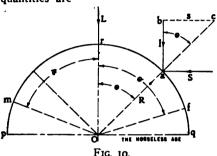

#### THE HORSELESS AGE.

in Fig. 9, is small, this latter point is of importance.

With the non-reversible engines at present running it is extremely bad practice to have oil grooves on both "on" and "off" sides of the bearing. What little oil does go in on the "on" side is promptly squeezed out on the "off" side.

#### IX.-SIDE CLEARANCE.

Let abc represent the semi-circular outline of one of the bearings, and efv the path of the cutter. Let the path of the cutter cut abc in dxx'd'. The known quantities are

$$x v = \frac{\pi}{3}$$
 "= 0.375",  
 $v c = \frac{1300}{1000}$ " = 0.015",  
 $o c = \frac{11}{8}$  "= 1.125",

and the quantities required are

w v = w x = radius of cutter.

w o = w o' =half thickness of liners.

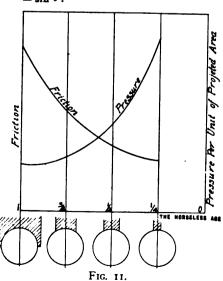

Let s be the mid point of x d and u of xv. Now, os and wu will be perpendicular to the chords xd, xv. Further, the two chords xd, ac of the circle abc meet in v;

$$xv \cdot dv = cv \cdot va$$

$$\begin{cases}
1 \times dv = \frac{15}{1000} \times (2\frac{1}{4} + 0.015) \\
\therefore dv = \frac{8}{3} \times \frac{15}{1000} \times \frac{2265}{1000} \\
= 0.1006'' \\
\therefore x d = 0.274'' \\
\therefore s v = 0.238''
\end{cases}$$

s u = s v - u v = 0.238 - 0.1875 = .0505. $o w = s u \cos \theta.$ 

$$\frac{s \, \nu}{\nu \, o} = \frac{0.238}{(1.125 + 0.015)} = \frac{0.238}{1.140} = 0.209$$
$$= \sin \theta.$$

...  $\cos \theta = 0.978$ ... o w = 0.0517... thickness of liners = 0.103

Again,  $w u \cos \theta + u v \sin \theta = ov = 1.140$   $w u \cos \theta + u v \sin \theta = ov = 1.140$   $w u \cos \theta + u v \sin \theta = ov = 1.140$  $w \cos \theta + u v \sin \theta = ov = 1.140$ 

$$w = \frac{1.101}{0.978} = 1.128.$$

But,  $w v^2 = w u^2 + u v^2 = 1.128^2 + 0.1875^2$ = 1.141".

Hence, the cutter diameter = 2.282, which is slightly over  $2\frac{9}{3}\frac{9}{5}$ , which is 2.28125.

Hence with a cutter one thirty-second inch larger than the crank pin diameter, and with liners one-tenth inch thick between the two halves of the box, the bearing can be backed off  $a_1^1 = (\frac{1}{1000})$  inch at the edge, and tapering back to nothing three-eighths inch from the edge.

THEORETICAL DISCUSSION OF SIDE CLEARANCE.

At a point a on the circumference of a journal of unit radius there is (neglecting friction for the moment) a normal reaction R balancing a portion of the load L, and the side thrust S which produces equilibrium.

The sum of the various products S equals L.

The side thrusts balance among themselves and merely produce friction.

Now  $b = R \cos \theta$ . Let  $\theta^1 = \text{limit of bearing}$ .  $\int_0^{\theta} l d \theta = R \int_0^{\theta^1} \cos \theta d \theta.$ 

Assuming R uniform.

$$\frac{L}{2} = R \sin \theta^1,$$

$$\frac{L}{2 \sin \theta^{1}} = R = \frac{\text{weight}}{\text{projected area of the bearing.}}$$

Actually, R is neither normal nor uniform, although in the middle portion it is very nearly both. Hence the 10° nearest the top r takes much more load than the 10° nearest the points p or q.

It will be obvious that removing the portions q f, p m, which do not take any bearing pressure, relieves the bearing of much side friction, and hence reduces the total friction. The increase in pressure on the remaining bearing is much less in proportion than the decrease of friction.

There is another reason for this decrease in the arc of contact, and that is that the oil is picked up better by the journal, a sharp edge tending to scrape the oil off.

The law connecting the friction with the relief is graphically shown in Fig. 11, and is expressed by the formula

$$F^1 = F \left( 4.7 \frac{\text{Relief}}{\text{Diameter}} \right)$$

where F = friction with relief, F' = friction without relief,

the relief being measured as projected on the diameter at right angle to the load (see Fig. 13).

#### NUMERICAL EXAMPLE.

Using the example worked out above Relief =  $2\frac{1}{4} - 2 \times \text{projection of } x \text{ } w \text{ (Fig. 8)}$ =  $2\frac{1}{4} - 2 \text{ (projection of } w \text{ } u \text{ -- projection } u \text{ } x \text{)}$ 

$$= 2\frac{1}{4} - 2 (1.101 - \frac{8}{18} \sin \theta)$$

$$=2$$
 \(\frac{1}{16}\times 0.209\)

Main Bearing

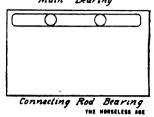

Fig. 12.—Oil Grooves.

$$= 2.250 - 2 (1.101 - 0.039)$$

$$= 2.250 - 2.124$$

$$= 0.126$$

= 0.120  

$$F' = F\left(4.7 - 0.056 \times 0.672\right)$$

$$\log_{4}.7 = 0.056 \times 0.672$$

$$= 0.0376$$

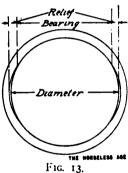

$$F' = F \times 1.090$$

F = 91.8 per cent. of F'

Hence friction is reduced by 8.2 per cent. Pressure is increased by 5.6 per cent.

### Elliptic Gearing for Magnetos.

A writer in an English contemporary (Motor Trader) suggests the driving of magnetos through elliptic gears to produce a more effective spark. It is well known that the maximum electromotive force induced in the armature of a magneto de-

pends upon the speed with which the lines of magnetic force are cut by the armature conductors. This speed is limited because in a four cylinder, four cycle motor two sparks are required per revolution of the crank shaft, and as the conventional magneto produces two sparks per revolution of its armature, the latter must be geared to turn at the same speed as the motor, which is very slow for so small a machine. By employing a pair of elliptic driving gears. which give a periodically variable motion. the armature could be considerably accelerated at the time the maximum induction occurs in it, whereby the electromotive force would be considerably increased. The strains of acceleration and deceleration of the armature would have to be counted with, but where the armature has only a low tension winding this may not be a serious objection.

### Theft of Equipment from Transient Cars in Garages.

A writer in our Communication Columns this week complains of the loss of articles of equipment from his car at various garages at which he put it up while touring. That such things as tools, clocks, pumps, jacks, etc., are not safe from theft when left on a car in the average garage is a well known fact, and various systems have been devised with the object of protecting regular customers. Transients, however, do not seem to have received much consideration in this respect as yet. Where the touring party is accompanied by a chauffeur, as is quite generally the case at present, he may be directed upon arriving at the garage to take off all parts not riveted down, and place them in a locker over night. The tourists themselves, however, if they travel without a chauffeur, can hardly be expected to do this, for upon arriving at the night stopping place they are usually tired and hungry and long for a bath more than anything else. A tedious taking down of parts not safe from theft, and the remounting of these same parts the next morning, would certainly detract much from the pleasure of a tour.

#### THE HORSELESS AGE.

The ideal way to avoid such annoyance to tourists is to provide individual stalls in garages into which transient cars may be run upon arrival, the key being kept by the owner until he wants his car again. Some of the newer garages in the big cities are arranged in this way. The plan would seem to have much to recommend it, particularly for garages catering to the tourists' trade, as with a constantly changing patronage the opportunities for stealing equipment are greater than in the average garage.

To the garage owner these complaints about articles having been stolen from the car must be extremely annoying, and if he knew a ready way of obviating the thefts he would certainly apply it. But the only effective remedy is the radical one of separate stalls. These, we have no doubt, will be supplied if demanded by patrons.

#### Grade Crossing Accidents.

Accidents to automobilists at grade crossings have been alarmingly numerous of late, and have generally resulted fatally. The abolition of grade crossings is making very slow progress, and it is really imperative that steps should immediately be taken to render the crossings safer by means of better warning signs. We have pointed out in these columns before that the present crossing signs do not fully serve the purpose from the standpoint of the motorist. They are too close to the track, and, besides, are generally not conspicuous enough.

It may be said that the driver is generally to blame for such accidents; that they can only happen if he does not exercise the necessary care. If the driver always kept a watchful eye on the road ahead and never exceeded the legal speed limit, these grade crossing accidents would probably be almost unknown. The frequency with which such accidents occur shows that drivers are wont to relax their attention on occasion, and this fact must be calculated with.

We believe that signs to warn automobilists of railroad crossings should be placed about a quarter of a mile ahead of the crossing, should be made as large as possible, painted in sharply contrasting colors and made to project a certain distance over the road, so it would be practically impossible to miss them. At night the signs should, of course, be properly illuminated. If such warning signs were erected at all crossings many fatal accidents might be prevented.

#### The Status of Aluminum.

It seemed a short time ago as though aluminum would be the standard material for all enclosing cases used in automobile construction. Ouite recently, however, there has been a considerable reversion to gray and malleable iron cases for the more important parts. These latter materials are more commonly used for crank cases than for other parts, though there are a considerable number of change gear cases and a few steering gear housings in which it is used.

There appear to be two important reasons why little or no aluminum is used in some of the recent cars. The tendency recently has been toward lower prices and economy in construction, and although aluminum is considerably cheaper than formerly, cast and malleable iron have also become cheaper. A cast iron case is probably always cheaper than an aluminum one, and a malleable iron case nearly always so, notwithstanding that the aluminum can be used nearly as thin as the other metals, is much lighter for a given bulk, and can be machined faster.

But while the lower prices of cast and malleable iron have favored their adoption, probably the most important consideration in many instances has been their greater reliability. Aluminum appears to be a metal whose qualities are largely affected by its impurities, a slight increase in their percentage making the casting liable to break under stresses much less severe than the usual tensile strength of the metal would lead one to expect to cause trouble. Some of the aluminum bought from the smaller foundries has proven weak, and this has affected the reputation of the metal generally. The larger foundries have, as a rule, given the trade most excellent metal, as they were enabled by quantity production to employ competent men to watch the entire molding process carefully. Excellent aluminum castings are also made in the foundries of some of the larger automobile manufacturers. It is earnestly to be hoped that the recently formed combine of aluminum manufacturers will standardize the manufacture of this metal to such an extent that it will acquire the uniformly good reputation which the many excellent qualities of properly cast aluminum deserve.

We also hope to see the production of the metal from its ores greatly cheapened so that even when it is given the necessary careful handling in the foundry the castings can profitably be sold at a much lower price than at present. Probably the impending manufacture of aeronautical devices will stimulate the study of the production of aluminum and its alloys, for the benefit of all classes of users.

#### Cast Steel Flywheels.

The flywheels of automobile motors have been until very recently almost universally of cast iron, but within a short time steel castings have been largely adopted for this purpose.

The main considerations in the design of a gasoline motor flywheel are twofold—the attainment of a maximum storage of energy in the rotary form, per unit of wheel weight, and the embodiment of a sufficient factor of safety to render practically impossible the bursting of the wheel under the action of centrifugal force.

A pound of metal incorporated in a flywheel is of value, so far as its storage of energy is concerned, in proportion to its distance from the axis of the shaft. The peripheral speed of a cast iron wheel is, however, strictly limited by the tensile strength of the material, and the maximum angular velocity being fixed by the characteristics of the motor, the maximum wheel diameter is thus definitely restricted.

In ordinary machine design the maximum safe peripheral speed of a cast iron flywheel is usually taken at about 6,000 feet per minute, a factor of safety of approximately ten being thus allowed.

For small wheels with solid webs, as used in automobile practice, this maximum safe speed is often taken as high as 7,500 feet per minute.

As the average modern automobile motor is capable of "racing" at as high a speed as 2,000 revolutions per minute, a cast iron wheel of slightly over 14 inches in diameter is as large as is usually permissible. A very wide and often quite a thick rim is therefore generally necessitated.

The greater tensile strength of cast steel (approximately three times that of cast iron) allows a much greater maximum peripheral speed to be employed, with no corresponding reduction in safety, or the same peripheral speed to be maintained and greatly increased security attained.

If the former alternative is chosen a considerable increase in diameter becomes permissible, the angular velocity remaining the same. The effectiveness of each pound of material in the wheel rim is thus increased, as stated above, and a wheel of given

steadying capacity can thus be produced of less weight in cast steel than in cast iron.

Wherever considerations such as road clearance and centre of gravity permit it would seem that the use of cast steel flywheels of somewhat larger diameter than the cast iron ones now in general use might be advantageous in the interest of weight reduction, despite the somewhat increased cost involved. A liberal increase in the factor of safety of such wheels could be made, and sufficient advantage in increased lightness still be secured.

In this connection it may be noted that flywheels with steel wire wound rims have been used for some time past by at least one automobile manufacturer in order to obtain the same advantages above noted as appertaining to the use of steel castings.

This tendency toward the adoption of steel in place of cast iron is simply one more of the many changes which have lately characterized the automobile industry, all of which are in the direction of a selection of the best adapted material for each particular application.

#### Renewed Interest in Carbon Steels.

When the use of alloy steels became common in automobile construction many designers apparently allowed their admiration of the qualities of some of the more expensive metals to get the better of their common sense. At least they used these alloys for many parts which would have been just as good if made from cheaper materials.

The recent trend toward lower priced and lower powered cars has forced makers of this class of vehicles to again employ a good grade of carbon steel for most parts. These steels first began to come into general use again as the material for sliding gears. Being found to give good service, with motors of moderate power, for these troublesome parts, the carbon steels have gradually been adopted for practically all the parts of the smaller and lower priced machines. Most makers have been forced by a consideration of the question of cost to investigate these steels, and have found that those makers who adhered to them all along have had comparatively little trouble.

So far as our knowledge of the materials being used in the cheaper cars goes—and it includes quite a number of machines—carbon steels, with rather high manganese and low sulphur and phosphorus, are used, except in a few places where especial compactness and strength is desired. These

special parts are usually made from chrome-

These changes in material are in line with the production of sensible machines for ordinary uses. But for cars of high power, or for users who wish extremely light machines and are willing to pay the price, the more expensive alloy steels will still continue to be used to a considerable extent.

It is unfortunate, however, that some few makers are apparently paying little attention to the quality of material they are using, and are making parts from metal containing enough sulphur and phosphorus to make it brittle and uncertain. Perhaps they are looking for present dividends rather than for future business.

# The Increasing Number of Agencies.

The development of the automobile business during the past few months is most noticeable to the average observer through the increase in the number of makes of cars handled in his home city. This is particularly true of the larger cities of the West and Middle West. Heretofore only a few of the larger manufacturers have been able to maintain agents in all the principal cities of this section, but from the number of agency contracts which are being closed for next season it is evident that even the companies of secondary size will be represented in most of the principal cities during 1910. Even agencies for makes which are not well known to the general public are cropping up here and there, and some of the so called next season's models are already being exhibited. During the coming year purchasers will evidently not be obliged to go very far from home to get almost any make they may wish.

#### Coming Events.

September 6-11—Lowell (Mass.) Annual Motor Carnival, Lowell A. C.

September 10 and 11—Motor Car Racing Association of Maryland Meet, Baltimore, Md.

September 11 and 12—Endurance Run from Philadelphia to Cape May and return. The Motor Company, Philadelphia, Pa.

September 15—Denver (Col.) Start of Flag-to-Flag Race to Mexico City, Denver M. C.
September 21—Riverhead L. L. N. V. Motor

September 21—Riverhead, L. I., N. Y., Motor Contest Association Meet.

October 7—Philadelphia (Pa.) Second Annual 200 Mile Stock Chassis Race in Fairmount Park, Quaker City M. C.

November 6 to 13—National Automobile Show under the auspices of the N. A. A. M. at Atlanta, Ga.

December 29.30—Philadelphia (Pa.) Annual Midwinter Endurance Contest Quaker City M. C. December 31 to January 7—New York City Annual Show, Grand Central Palace, American Motor Car Manufacturers' Association.

# Maintenance and Repairs

# Useful Points from Driving Experience.

By A. D. HARD,

Small particles of foreign matter getting on the surface of the contact roller of the timer will often cause irregular missing of a perplexing nature, or irregular current passage which will result in lack of power from that particular explosion, causing a jerky action of the motor. To remedy this condition hold the contact roller against a revolving emery wheel at a slight angle from its natural path and the surface will become bright and smooth in one minute.

The points of a split pin may be made to stay snugly together for reinsertion by slightly spreading them with the point of a knife blade inserted near the shank, and then pinching the points together with the pliers. When the knife blade is removed the points will hug each other beautifully.

In testing dry cells when connected up never place the instrument directly upon the carbon. It is not a good conductor, and will mislead. The better way is to see that the nut on the small brass bolt through the carbon is tight, then connect to that. If the bolt is loose the cell will not test up to its proper amperage. If the connection is doubtful, test by touching the carbon point of the instrument to the zinc of the next cell following.

The water jackets of cylinders which have been cracked by freezing of the cooling liquid until they leak may be quickly and cheaply repaired by screwing on a thin piece of metal plate made to conform to the shape of the cylinder with a piece of ordinary steam packing underneath. (This would not be a particularly neat repair.— Ep.)

An otherwise unexplainable knocking may be due to a new connecting rod bearing which is not exactly true. The effect will be to throw the piston against the side of the cylinder at each explosion.

Overheating at high speed of the motor when running on low gear may be greatly reduced by putting the spark well ahead and slowing the motor speed as needed by the throttle. This cuts down the amount of fuel used and consequently the heat units produced.

Some forms of carburetor have two springs on the supplementary air inlet, one being a soft spring which will hold the air inlet closed with but little force in order to make the motor start easily. The other spring is a much stiffer spring which should not exert its force until the energetic suction of high speed renders the softer spring useless to draw sufficient fuel for the more rapid action. Tightening up the soft spring gives more fuel at slow speed, tightening up the stiffer spring increases the fuel supply

at high speed. A popping noise in the carbuhetor is a call for more fuel.

A pressure gauge upon the pump is a very uncertain way of determining the air pressure in a tire. The resistance to the ingress of air is added to the tire pressure in such a gauge. The gauge should be applied to the valve opening after the pump is removed.

A small amount of lubricating oil mixed with the gasoline will improve compression and be an insurance against failure of the regular lubricating mechanism, but too much oil in the gasoline will interfere with the proper action of the carburetor. In my opinion one half pint of thin lubricating oil in 5 gallons of gasoline is sufficient for best results.

An old inner tube which has been patched until it is unreliable may be slit open around its concave side and placed over a new inner tube with great advantage to the life of the new inner tubes.

The only safe way to crank a motor is to have the compression and ignition come while the crank is being pulled up. It does not make any difference which hand is used. Safety depends upon having the resistance against the flexed fingers, so that if a back kick comes it will simply pull the hand open and do no harm. Directions for using the left hand instead of the right are misleading, in so far that if you push down with your left hand you are liable to get your left arm broken.

A switch on the steering wheel by means of which you can cut out the ignition when rounding corners, coasting and passing pumps, is a valuable little addition to a car.

### Truing Up a Brake Drum. By A. P. Press.

Perhaps there is no part of a car the dependable operation of which is so conducive to that cool nerve which is so essential to good driwing as is a good brake—a brake that will hold when wanted to, and will let go when the pressure is relieved. If the brake drum is "out of true" no brake will "feel" good, and the object of the present article is to show how the drum can be made to run true.

If the drum is made integral with the hub casting, as it is in some of the smaller cars, it can only be trued in the lathe, which is a machine shop job, but if it is bolted to the spokes it can be made to run as good again as when it left the wheel maker's, and perhaps better.

Jack up the car at the side where the drum is out, so the wheel can be taken off and the drum removed. Put the wheel back and put the wheel nuts on. Take the wheel and true off the seat where the drum goes. This can be done by using a rest and a sharp chisel. It will take two persons to do this, one to turn the wheel and the other to hold and use the chisel, the same as in wood turning.

The spokes being faced off, take off the terested in the great modern problem wheel and put on the drum with two small marketing goods should procure a copy.

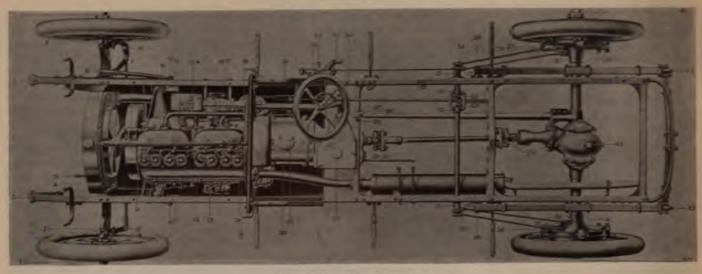

bolts. That is, if the wheel bolts are threeeighth inch use a five-sixteenth inch bolt and tighten as hard as you can, and still move the drum with a smart blow with a wood mallet. Put the wheel back on the axle and turn it the same as you did in truing off the spokes, holding a piece of chalk on the outside of the drum, if the brakes are of the contracting type, or inside if they are of the expanding type. Strike on the high side with the mallet to knock the drum true, and try with the chalk again. Continue in this manner until the wheel runs perfectly true, and tighten the two bolts very tight. Now, take a twist drill or a reamer the size of the wheel bolt (don't try to use a carpenter's bit) and ream out each hole true with the hole in the drum. The drum being of metal, it will guide the reamer to cut the hole in the spoke true with itself. Now take the wheel bolts and put them in, taking care to put them in opposite to each other, and to tighten them equally hard. Put in four bolts in this manner, and then ream and put in the other eight bolts. If the bolts are all too large to fit the holes dip them in white lead. This will make them hold and also stop them from rusting. A drum can be trued in this manner to within 1-100 of an inch, which is near enough for all practical purposes.

#### The Asbestos Industry.

According to a brochure just issued by the United States Geological Survey the United States leads all other countries in the conversion of raw asbestos into manufactured products, although much less than I per cent. of the material used is mined in this country. There are only two active mines in the United States at present, one in Vermont and one in Georgia, although asbestos is found also in the Grand Canyon of Arizona, in Wyoming and in California. Canada is the greatest source of raw asbestos, which is imported duty free for the manufactories of the United States. Canada's production for 1908 amounted to 65,-534 tons, of a value of \$2,547,507, while the total output of the United States during that year was 936 tons, valued at \$19,624. Imports of unmanufactured asbestos into the United States in 1908 amounted to \$1,-068,322, and manufactured \$127,548. Russia has recently become an important producer of asbestos, her 1907 production being 10,308 tons.

#### Address on Advertising and Selling.

The address on advertising and selling delivered by Hugh Chalmers, president of the Chalmers-Detroit Company of Detroit, Mich., before the Associated Advertising Clubs at their recent Louisville meeting, has attracted the widest attention because of the unusual amount of practical sense and worldly wisdom that was packed into a short talk. The address will no doubt appear in pamphlet form, and anyone interested in the great modern problem of marketing goods should procure a copy.

#### A Practical Oiling Index.

The above table represents a double page from the new instruction book issued by the Stevens-Duryea Company, of which a copy has been received at this office. This double page contains complete instructions for oiling all parts of the car. The nlan view of the chassis shows all parts that to be oiled, properly numbered, and

the lettering on the chart gives the name of the part thus indicated, the form of lubricant required by it, the frequency of attention required and the number of similar points on the chassis. This form of oiling index seems to be very practical, and may be recommended as a guide to others whose duty requires them to prepare instruction books.

### American Expositions in Germany.

Two expositions of American manufactures are to be held in Berlin next year. One of them is known as the American Exposition, Berlin, 1910, and will be held during the three months-April, May and June. An American office has been established in the Hudson Terminal Building, 50 Church street, New York, and Max Vieweger is American manager. According to German custom on such occasions, an honorary board of directors has been appointed, and Prince Henry of Prussia has accepted the presidency of the exposition, while J. Pierpont Morgan and Thomas A. Edison have joined the honorary American committee. We are informed that the two large German transatlantic lines offer a reduction of 30 per cent. on freight intended for the exposition. Arrangements have also been made whereby exhibitors who do not want to send a man specially to Berlin can have their exhibits unpacked, installed and demonstrated, for a moderate charge, by a special sales office and Bureau of Information established in the Exposition Building.

The other exposition referred to is known as the American Permanent Sample Exhibition at Berlin, and is conducted by the American Exhibition Company, 77-79 Broad street, New York. This exhibition, which is to be opened in the spring of 1910, is designed primarily as an exhibit of distinctively American products, and the management especially desires American manufacturers of novelties to take part.

#### Triumph of the Taxicab in London.

Vice Consul General Richard Westacoff reports that in a written reply by the British Home Secretary to a recent question the rapid rate at which the horse drawn cab is giving place to the taxicab in London was strikingly indicated. The number of licensed hansom cabs on July 1 was 4,039, a decrease of 1,290 in one year; four wheeled cabs, 3,379, a decrease of 389; motor cabs, 3,394, an increase of 1,886. It will thus be seen that in one year the number of taxicabs has more than doubled,

# NEW VEHICLES

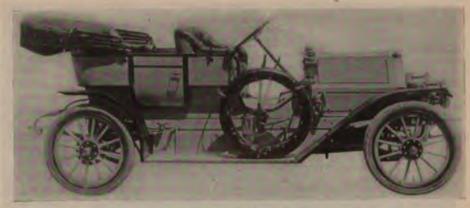

The Badger Car.

In our last week's issue we gave the specifications of the car to be turned out by the recently organized Badger Motor Car Company, of Columbus, Wis., and we are now enabled to print a photograph of the car, complete, and a side view of the chassis. The vehicle is equipped with a four cylinder Northway motor of 4 inch bore and 4 inch stroke. The motor, clutch and change gear are assembled into a power unit, which is carried on a sub-frame. The cooling water is circulated on the thermo-siphon principle, and a flat belt driven circulating fan is located back of the radiator, carried by a self adjusting bracket secured to the forward engine cylinder. The carburetor is a Schebler, and is located on the left hand side of the motor, connecting through a two branch manifold to the inlet ports. A Bosch high tension magneto is fitted for ignition, and the spark plugs are located over the inlet valves. The motor is lubricated by splash, an oil reservoir being provided at the bottom of the crank case, and the oil kept in circulation by a pump. The spark time is fixed, and there is consequently no spark lever on the

The clutch is designed to run dry, but the clutch operating mechanism and the change speed gears operate in a bath of oil. The gears of the change gear are forgings made from open hearth steel. The shafts of the change gear are carried in F. & S. ball bearings. The drive to the rear axle is by a shaft encased in a tube, which acts as a torsion brace. There is only a single universal joint in the drive to the rear axle, at the forward end of the propeller shaft.

The frame of the car is of pressed steel and is very slightly narrowed in front. It is carried by semi-elliptic springs in front and three-quarter eliptics in the rear. Particular care has been exercised

BADGER CAR.

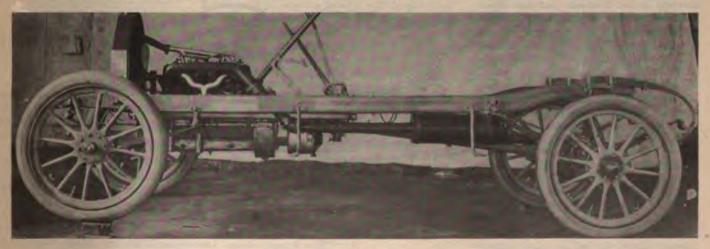

in the design of the spring joints. The spring eyes are fitted with bronze bushings, the spring shackles and bolts are case hardened, and all of the spring joints are provided with grease cups. The rear axle is of the semi-floating type, and of such design that the universal and driving gears may be removed without taking the axle apart. The front axle is a one piece drop forging of I section, with Elliott type steering heads. The steering gear is of the worm and gear type, and the tie rod is located back of the axle. Two independent sets of brakes act on drums secured directly to the rear wheel hubs. These brakes are of the internal expanding and external contracting patterns, respectively, and the braking action on the two drums is equalized by means of pressed steel balance levers extending all across the frame.

The control devices are arranged along conventional lines. There are the usual change gear lever and emergency brake lever just outside the driver's seat, the inclined steering post, clutch and service brake pedals, and an accelerator pedal, and a throttle finger lever on top of the steering column. The change gear is controlled on the selective plan, and its enclosing housing is relatively compact. The car will be seen to conform generally to current conventional practice and forms one of the many "Thirties" which this season has brought forth.

#### Pressed Steel Automobile Parts.

The first part of automobiles to be made of pressed steel was undoubtedly the running gear frame, and this particular important part is now almost exclusively made by this manufacturing process. Before pressed steel frames came into use motor car frames were made either of angle steel or of wood reinforced with sheet steel flitch plates. As compared with the angle steel frame the pressed steel frame was undoubtedly stronger for a given weight, and it also was much sightlier. The possibility of varying the height of the section along the length of the frame member in accordance with the variation of the bending moment afforded a striking theoretical advantage, but we are inclined to think that the smoother finish and generally superior appearance were the chief cause of victory of the pressed steel over the structural steel frame.

With the comparatively recent advent of automobile production on a very large scale has come an interest in the production of other parts than the frame members from pressed steel. Pressed steel rear axle housings are now used to a considerable extent. Unless we are mistaken this construction originated with the Fiat Company, who introduced it when they brought out their first light car about two years ago. The Fiat axle consists of two pressed steel halves which are bolted together. Since that time the autogenous welding process

CHASSIS.

ning must be renewed after fifty to rings.

e Duryea Delivery Wagon.

The dashmects with the horn tube by means andard thread, and will fit any horn

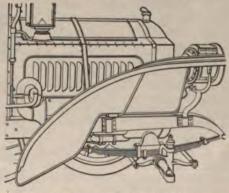

BUGGYAUT DELIVERY WAGON.

tube. The tube runs underneath the car, and only the horn is outside the car.

The Wordingham auto signal consists of a combination of the brass dashpot just described and an all-brass two toned whistle. The whistle is directly connected to the dashpot, and the entire device is secured underneath the footboard. The whistle can be adjusted to any tone, and then locked. Simplicity, good wearing qualities, low cost and independence of engine are claimed to be the chief advantages of this signal.

# The B. & L. Trailing Steering Spindle.

A steering knuckle so constructed that the centre line of the hub spindle does not intersect the centre line of the pivot pin, but lies a certain distance back of it, is being exploited by the Queen Manufacturing Company, of Webster City, Ia. It is claimed for this construction that in case the connection to the steering post should break the steering wheels will keep in the straight ahead position long enough to al-

THE B. & L. FRONT AXLE TRAILING SPINDLE.

low the driver to stop the car. The distance between the centre lines of the vertical and horizontal spindles is 2½ inches. The company owns patents issued January 9, 1901, and November 1, 1898, which are claimed to cover the construction. We understand that negotiations are now pending with the Mason Motor Car Company, of Waterloo, Ia., with respect to the use of the device on Mason 1910 cars.

Harvey Auto Springs.

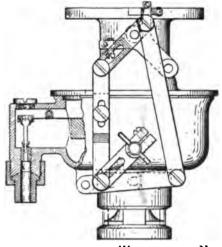

The Harvey Spring Company, of Racine, Wis., have entered the field with a line of automobile springs, comprising semi-elliptic, full elliptic and scroll and elliptic types. The semi-elliptic springs are furnished, as a rule, with rebound clips, and either with

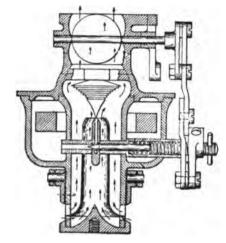

HARVEY AUTOMOBILE SPRING.

or without a centre bolt. Where no centre bolt is used the plates are held together with a clip in the centre when shipped, while when in place on the car they are held together by the regular axle clips. In place of the usual bolt there is a small bead in each plate that fits into a depression in the plate below to keep the plates from shifting. It has been found that one of the weakest points of the ordinary spring with a centre bolt is at the centre, and the boltless construction considerably increases the strength.

The scroll end elliptic springs are used

WACKENHUTH NON-SPRAYING CARBURETOR.

in place of the regular full elliptic type. These springs are claimed to ride easier on account of the extra length of the upper half.

### The Wackenhuth Non-Spraying Carburetor.

The Wackenhuth Carburetor Company, 26 Hackett street, Newark, N. J., manufacture a carburetor in which the stream of gasoline issuing from the nozzle is spread over a cone a portion of whose surface is serrated. The carburetor is of the concentric float type, and constancy of mixture is assured by means of a needle valve in the passage to the gasoline nozzle and a sliding sleeve which obtrudes the air openings more or less. The sliding sleeve, gasoline needle valve and throttle valve are interconnected by an adjustable linkage. It is claimed that the gasoline is spread evenly over the surface of the cone in a very thin film, and the air in passing the surface of the cone absorbs the gasoline, whereby a uniform mixture is produced. In order to adjust the linkage connecting the throttle valve with the gasoline needle valve and the air inlet valve, the engine is first run

CHAMPION AUTO ENGINE CLEANER.

on small throttle at slow speed, and the needle valve is adjusted to the proper position for these conditions of running. Then the engine is run on open throttle at full speed and under full power, and the needle valve is again adjusted to the position in which it gives a correct mixture. Then the linkage is so adjusted that it will bring the needle valve to the correct positions for both low and high speed operation. The manufacturers especially recommend the carburetor for use on two cycle motors, and claim that it will prevent back firing into the crank case.

#### The Champion Auto Engine Cleaner.

The Lennox Chemical Company, of Cleveland, Ohio, are manufacturing an outfit designed to facilitate the cleaning of automobile engines and other greasy and dirty machine parts. It consists of a seamless galvanized steel tank, with a gauge and safety valve, a spray nozzle with strainer and cock, and a length of flexible metallic tubing to connect the spray nozzle with the tank. The outfit is furnished with one of two sizes of tanks, of six and eight gallons capacity respectively. When it is to be

used the tank is filled half full with gasoline, and compressed air at a pressure of 80 to 120 pounds per square inch is admitted to the upper portion of the tank through the gas inlet provided for the purpose. The air can be obtained from the tire inflating installation found in most garages When the gauge on top of the tank shows the desired pressure, the inlet cock is closed and the nozzle cock opened, whereupon the sprayer may be put to use. It is customary to work from the top of the engine down. It is claimed that the high pressure stream of gasoline cuts and dissolves the caked grease and dust on the engine and cleanses the engine thoroughly. By means of the sprayer all parts of a car can be conveniently reached. It is

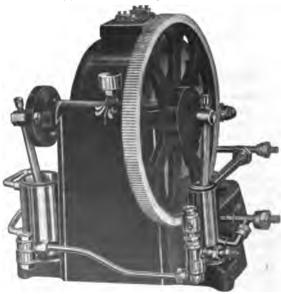

open air, and users are warned to guard against a hot engine, lighted lamps, cigars, etc. Kerosene or soap suds can be used instead of gasoline, if desired. The use of the outfit is said to result in a great saving in gasoline as compared with the usual method of applying the liquid in cleaning greasy parts. It also greatly expedites the cleaning process. This cleaner is handled by the Bishop & Babcock Company, Cleveland, Ohio.

# The Eureka Automatic Compound Air Pump.

This is a new electric air pump recently placed on the market by the Bishop & Babcock Company, of Cleveland, Ohio, for the use of public and private garages. The pump is known as the No. 12, and is claimed to automatically maintain a constant air pressure of 100 pounds, or less if desired. Pumping into an 18 gallon tank, the pump will furnish enough air to inflate one tire per minute, and the capacity of this pump is said to be sufficient for the largest garages.

The construction of the pump is well shown by the illustration. The electric motor is back geared to give a low rate of revolutions of the countershaft. The countershaft carries a crank pin at each end from which the low pressure and high pressure pumps are operated. The pump cylinders are secured to the base of the electric motor. The pumps are made entirely of bronze, and have bronze valves and connections.

The pump is controlled by an automatic switch, illustrated by one of the cuts, so it will operate only when the pressure in the tank is below that for which the switch is set. The pump will fill an 18 gallon tank to 25 pounds pressure in three minutes; 50 pounds pressure in eight minutes; 75 pounds pressure in twelve minutes and 100 pounds pressure in sixteen and one-half minutes. The pump cylinders are of 1½ inch and 2½ inch bore, respectively, and both pis-

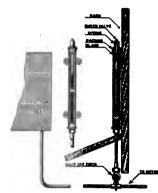

recommended to use the outfit in Eureka Automatic Compound Electric Air Pump.

tons have a stroke of 3 inches. The motor is either a one-third horse power alternating current motor or a one-quarter horse power direct current motor. The countershaft turns at 150 r. p. m.

#### The Hub Tank Gauge.

This gauge, which is manufactured by H. W. Hubbard, Middletown, Conn., consists of a heavy glass tube enclosed in an outer metal sleeve, cut away in front to show the level of the liquid, and held in position by gaskets to make a liquid tight joint and absorb all vibration which might

HUB TANK GAUGE.

have a tendency to break the glass. The lower end of the metal sleeve is connected, by suitable tubing containing a shut-off cock, to the pipe line to the carburetor, the gauge being placed in any convenient location, as on the dashboard.

The special feature of the gauge is a loosely seated check valve in the top of the metal sleeve, over the gauge glass, which allows the air contained in the glass tube to escape slowly, but in case of violent jolting closes and prevents spilling of gasoline.

### Packard Company Reorganized With Increased Capital.

The Packard Motor Car Company, of Detroit, was originally started some eleven years ago as a West Virginia corporation. It became a Michigan corporation September 1, 1909. In reorganizing the company under the Michigan laws, the capital stock became \$5,000,000 preferred and \$5,000,000 common. The enlargement of the capital stock is made to meet the company's needs for enlargement of floor space and additional facilities generally, in order to enable the company to avoid night work.

# Overland Company to Increase Capital Stock.

According to a report from Toledo, Ohio, the officials of the Overland Automobile Company are completing a plan of reorganization of the company. The present company is an Indiana corporation, and is capitalized at \$800,000. The acquisition of the Pope plant in Toledo made it necessary to considerably increase the amount of capital, and it is said to be the intention of the officials of the company to give up their Indiana charter and to reorganize under

the name of the Willys-Overland Company, with a capital stock of \$2,000,000.

The company plans to turn out 16,000 cars next year, of which 10,000 are to be manufactured in Toledo and the rest in Indianapolis. The new Overland model will be of 20-24 horse power, and will be provided with two, three and four passenger bodies. At the present time considerable new machinery is being installed in the Toledo factory to facilitate the rapid production of cars. Mr. Willys, president of the Overland Company, is said to be endeavoring to induce T. W. Warner, of Muncie, Ind., formerly of the Warner Gear Company of that city, to locate in Toledo. Mr. Warner is organizing the Warner Manufacturing Company, for the manufacture of change gears, and it is stated that Detroit and Muncie are making bids for the plant.

# H. E. Wilcox Motor Car Company Increases Capital.

The H. E. Wilcox Motor Car Company. of Minneapolis, Minn., has been reorganized with a capital stock of \$1,000,000. It is understood that the company will be continued as a closed corporation. John F. Wilcox, father of H. E. Wilcox, and C. H. Davidson, of Carrington, N. Dak., it is stated, will supply most of the additional capital. Work is to be started at once on a new four story brick factory building, 300x80 feet, at 1030 Marshall street N. E., adjoining the present plant of the company. Next year 1,000 cars are to be built. P. W. Strong, sales manager of the Welch Motor Car Company, Pontiac, Mich., will join the Wilcox Company. At present the company employs only about fifty men, but after the completion of the new building it will give employment to about a thousand, as it will then manufacture most of its own parts, instead of merely assembling parts of cars bought in the market.

# Middleby Company to Produce a Six Cylinder Car.

The Middleby Automobile Company, Reading, Pa., are to bring out a six cylinder machine about October 1, with 120 inch wheel

base, 36x4 tires and 40 horse power motor. The car, fully equipped, including top and wind shield, will sell for \$2,000. It will be made as a roadster or a touring car as desired. During 1910 they expect to turn out 350 cars, having a brick addition 156x52 feet now under way.

# Automobile Road from Washington, D. C., to Atlanta, Ga.

A tier of counties in Virginia, the Carolinas and Georgia are working in a cooperative way to make a continuous good auto road between Washington and Atlanta. At Washington it will connect with the macadam road which Maryland is constructing via Baltimore to the extreme northeastern corner of the State on the way to Philadelphia and New York.

The counties are spending \$1,000,000 on roads and bridges. Their aim is to make a road which will attract auto tourists, especially during the winter months, when there is no other tour possible in the United States. It is claimed that the road will greatly stimulate automobile sales during a season which is usually quiet. The road is to be free, except at two or three toll bridges.

Each county improves its own link. About 300 miles of the road have been completed, and work is progressing in more than twenty counties. From Richmond south the route lies below the usual snow line, touching Raleigh, Columbia, Aiken and Augusta. The materials being used do not freeze or become muddy. At intervals of a day's journey there are high class winter resorts for the accommodation of tourists. Leonard Tufts, of Pinehurst, N. C., is president and Frank Weldon, of Atlanta, is secretary of the association which has induced the counties to take up the work.

Samuel H. Daddow, formerly with the Acme Motor Car Company, Reading, Pa., has bought a half interest in the business of E. S. Youse, same place, which will hereafter be conducted under the name of Youse & Daddow, wholesale and retail auto supplies. They will also act as local agents for the Hudson and Chalmers-Detroit lines.

RAMBLER EASTERN 1910 TEST CAR.

An account of the test run of two of these cars was given in our issue of August 25.

# The Electric Vehicle Field from the Standpoint of the Central Station.

The Electrical World of New York, a leading electrical journal, publishes in its August 5, 1909, number the results of an investigation which it has been making relative to the extent and conditions of use of electric vehicles, with special reference to the relations subsisting between electrical supply companies and the electric vehicle.

Inquiry sheets, including eighteen questions, were sent to about 4,000 central stations in all parts of the country, and answers were received from about 1,500 of the companies thus addressed. The questions asked had reference to whether the central station addressed was taking any part in pushing electric vehicles, the extent of the local use of these cars, the prices charged for charging current and for garaging, the number of local garages having facilities for caring for electrics and several other topics.

The general object of the inquiry, in addition to securing statistics, was to awaken interest among electric light and power companies in the electric vehicle as a source of revenue. The report is well worth reading by everyone who takes an interest in electric motor cars. Some of the facts brought out are briefly summarized here.

A very considerable proportion of the corporations addressed reported "nothing doing" in the electric vehicle line in their localities, and it is evident that there are large sections of the country where the electric is practically unknown, especially in the South and West.

In a large number of instances the districts reported upon were regarded as too hilly or too sandy to make the introduction of the electric a practical matter, and in certain cases the few electrics which had been introduced were reported to have been discarded in favor of gasoline cars.

In some of the smaller and less favored towns of the South and West the streets were reported to be of such a wretched character as to be impracticable for electric vehicles, or indeed for automobiles of any motive power.

Quite a number of correspondents stated that their towns were too small to render the use of exclusively town vehicles desirable, and that the surrounding country was unfitted for electrics.

Certain replies also indicated that the gasoline vehicle had acquired the whole local field, and that a strong prejudice existed against the electric, or at least an almost complete lack of information regarding its capabilities. High initial cost and limited radius of action appear to have been the shortcomings generally urged against it.

From the replies received it appeared that about 500 of the companies addressed were more or less awake to the possibilities of the electric vehicle field, and it is a significant fact that these companies represent

forty-one States and Territories of the Union.

About 250 of these corporations sent in definite information as to their activities in this line, ranging from an intended entrance into the charging field to an aggressive campaign for business. A number of these central stations expressed themselves as desirous of handling electric vehicles, and others of securing full data regarding their operation and charging.

According to data secured it is safe to say that there are about 10,000 electric vehicles in use in this country, and that \$50 per annum represents, on the average, the cost of the energy for charging each of these. About \$500,000 thus approximately represents the sum paid out for electric vehicle charging the country over.

It is estimated that slightly over 10 per cent of these vehicles are charged from isolated electric plants, the remainder being charged at public garages obtaining their electric energy from central stations.

A considerable number of companies report themselves as interested in the introduction of rectifiers in garages and elseswhere, but not directly concerned with the development of the vehicle business.

The rates made by electrical supply companies for energy to be used in vehicle battery charging vary very widely, and generalizations upon the subject are very difficult. Among 103 companies making flat rates, which vary from 2 to 20 cents per kilowatt hour, the average is not far from 71/2 cents per kilowatt hour. Where sliding scales, involving two or more rates depending upon demand, are adopted, a wide diversity of practice is to be noted. Such scales vary from 15 to 7 cents per kilowatt hour to 6 to 2 cents per kilowatt hour, a rate of 10 to 2 cents per kilowatt hour being somewhere near the average. Some companies make rather complicated rates, consisting of several scaled rates, dependent upon demand, systems of discounts and stipulations as to hours during which current is not to be used. Maximum demand meters are used to some extent, and time switches to cut off the supply during "peak"

As is perfectly natural, public garages seem to be favored in the matter of rates over private owners, the latter class paying nearly, if not quite, twice as much for current in many instances as the former. In the case of sixty-eight companies the garage rate and the private consumers' rate are in somewhat the ratio of 5 to 8. The minimum consumption required to secure the low garage rate is, of course, large as compared with the minimum consumption demanded of private users.

The data obtained indicate that garages frequently sell electric energy to their customers at double the price they pay for it, and that most garages make a good profit on the sale of electric current.

Investigation into the garage rates for combined charging, washing and delivering.

in all parts of the country, indicates that these flat rates range from \$20 to \$35 per month in cities and towns of ordinary size, and from \$30 to \$55 in the very largest cities. The lower rates appear to be found, as a rule, in the smaller places.

Sixty-one of the companies replying reported that they received some direct income from the charging of ignition accumulators, the station exciters, a bank of lamps or a small rectifier being employed. Revenues from this source ranged from \$5 to \$600 per year, and the prices charged per battery from 50 cents to \$1.

Although it is estimated that there are from 2.000 to 3,000 electric business wagons and trucks in use in this country, only a very moderate proportion of these are owned by central stations, where one might think they could be used very advantageously and act as an incentive to their public adoption. A few companies only, mostly in the larger cities or in places where the electric vehicle has attained prominence, employ officials whose time is exclusively devoted to the promotion of electric vehicle interests.

#### Ford 1910 Announcement.

The Ford Motor Company, of Detroit. Mich., will continue their Model T for 1910. The car will be furnished in three open and three closed styles, at the following prices: Roadster, \$900; tourabout and touring car, \$950 each; coupé, \$1,050; landaulet, \$1,100; town car, \$1,200. It will be observed that the prices of the open cars have been increased over those of 1909, but the equipment which will be furnished with these cars is more complete than it is this year. The equipment of the open cars will include an unlined top, an automatic brass wind shield, a speedometer, two gas lamps, a generator with connections, two side oil lamps, a tail lamp and a tubular horn. The equipment of the closed car will include two side oil lamps, a tail lamp and a tubular horn. The new prices will go into effect on October 1.

Obituary.

Edward M. Murphy, of Pontiac, Mich., president of the Oakland Motor Car Company, died at his home in Pontiac last Saturday of apoplexy, after only a few hours' illness. Mr. Murphy was born in Wayne, Mich., December 19, 1864, and lived there until twenty-three years of age. In 1888 he formed a partnership with C. V. Taylor, and started the first buggy factory in Pontiac, Mich. Withdrawing from the partnership in 1893 he organized the Pontiac Buggy Company, and served as president and general manager until about a year ago. when the company was consolidated with the Dunlap Vehicle Company, Mr. Murphy becoming president of the new company. In 1907 Mr. Murphy organized the Oakland Motor Car Company, which was sold to the General Motors Company a few months ago. Of late he had superintended the moving of the buggy company to Rockford, Ill.

# Commercial Applications.

### Taxicabs in San Francisco. By I. N. B.

BY 1. N. B.

San Francisco, always one of the greatest automobile cities in America, has taken to the taxicab with great avidity. Though the first taxicab company began actual operations in this city less than a year ago, there are now five concerns serving the public, and there is talk of others entering the field, and there are quite a number of privately owned taxicabs operated by chauffeurs who thought they could do better operating for themselves or by hackmen who found that the horse cannot stand the competition.

Besides this, there is not one of the companies now in existence that has not more machines on the way. There is talk that the business is being overdone, and that some of those operating taxicabs must meet the inevitable result of oversupply in any business, but the remarkable growth of San Francisco must be considered in weighing this pessimistic view, and the fact that it is essentially a "riding" town, not only because of its many hills, but because it is the nature of its people to ride, and because from year's end to year's end it is the resort of tourists from all parts of America and the world.

The average rate for a single passenger here is 50 cents for a half mile or fraction thereof. Some charge 60 cents. There are flat rates by the hour, being generally \$4 inside the city and \$3.50 for beach or park pleasure riding. For handbags carried outside the rate is 20 cents, and for a trunk, also outside, 40 cents is charged. Most of the companies run their cabs from 65 to 80 miles a day. The cabs of one of the newer companies make a mileage of 30 per day at present.

It seemed to take quite a while for taxicabs to get a footing in San Francisco after their introduction was first broached. Several companies were formed with a flourish and went out of business, after selling large quantities of stock by heavy advertising. Some of the purchasers of these stocks drop into the bona fide companies' offices even now on occasions and ask whether they can be given any clew to a dividend, but the companies seem to have faded away entirely, and the buyers have only experience as their return.

The first taxicab company to enter the field in San Francisco, that is to actually start cars running, was the Pacific Taximeter Cab Company, of which Fay C. Beal is secretary, treasurer and manager. It began operations only last January, starting its first cars on the 16th of that month. It has prospered from the beginning, and now has eleven cars running, and expects

to have nineteen more within the next few months.

The Pacific Company uses the French Renault machine exclusively. The cars are designated by an orange stripe. The garage occupies the whole lower floor of a brick apartment house at 1355-1363 Bush street, near Polk. It is large, but has no special features. The offices are at the same place. In fact, all the taxicab companies but one have their main offices at their garages. The Pacific Company has but one public stand, on Market street, in the business centre. It has a connection with the St. Francis and other hotels.

This company furnishes oil free to its drivers, but they are required to pay 15 cents a gallon for their gasoline, which is the present market rate. There is a measuring machine at the garage, and the day repair man has the key to the tank. Whatever gasoline is sold is signed for by the driver, and the account of each is turned in at the end of the week. The night repair man measures out gasoline similarly, and every morning the amount in the tank is balanced.

For quite a time the company kept no particular check at night, permitting the drivers to take what gasoline they needed and leave tags for the amounts. The haste of the drivers caused serious inaccuracies, for the company found that under this system it was facing an expensive deficit in gasoline each month. A night repair man was then put on, and since then there has always been a correct balance.

It was through Manager Beal of this company that the new ordinance, doubling the number of cab stands on the public streets, was adopted.

The Pacific Company is financed entirely by local capital. George P. Fuller is the president, and the other officers are Frank P. Hooper, vice president; Fay C. Beal, secretary and treasurer; Clarence R. Ward, Carroll N. Beal, Lawrence W. Harris and Rene J. Marx, directors.

#### THE TAXICAB COMPANY OF CALIFORNIA,

with a large wooden garage at 1618-1630 Jackson street, just off Van Ness avenue, has twelve taxicabs in operation now, and Manager W. E. Travis says twenty-five more will be received shortly. He says that the company will eventually have fifty in operation—most likely within three months.

The Jewell-Keeton is the principal machine used by the California Company. It has eleven of these, one Renault and one Clement-Bayard. This company has the largest number of outside stands of any in the city at present. In fact, it is the only one that does not do nearly all its business from its main office or garage, though it has three stands in prominent parts of the city.

The California Company makes a specialty at present of standing machines at the leading hotels, and its connections with these hostelries bring it a heavy business. It has stands at the St. Francis Hotel, the

Fairmont, the Stewart and the Manx, and even at the new Palace, which is not yet opened to the public. It maintains five others, one at the Union Ferry Station, where the great tide of traffic from outside and "across bay" pours into the city; one each in front of Tait's and Techau's fashionable downtown cafés; one at the White House, in the centre of the retail shopping district, and one in front of Donlon's drug store, at Sutter and Fillmore, which is the heart of the business section that sprang into life immediately after the fire and still has much activity, though the larger businesses have all moved downtown. With these stands the city is pretty well covered by this company, but it is contemplating establishing many more under the new ordinance increasing the number permitted. Those stands now used were obtained under the old cab ordinance, and are mostly locations where the horse drawn carriages that once held them have given way to the motor.

This company supplies its drivers with oil free of charge, but has a "service" system with gasoline. Some of the drivers get the gasoline at half cost and some pay full. This is according to time and diligence of service. An accurate register is kept, the Bowser tanks being used. A record of the amount measured out and the men to whom it goes, who are segregated into classes according to the service rule, is kept, and this roll is turned in each day and entered in a tabular book kept for the purpose.

W. E. Travis is the president and general manager of the company. The directors include Robert Murphy, George Wingfield, L. M. Hoeffler and R. L. Coleman.

The California Company advertises a flat weekday shopping rate of \$3 an hour, from 9 to 12 m., in the district east of Van Ness avenue, which contains all the principal stores.

#### THE TAXICAB AUTO LIVERY COMPANY

is the name of an active and prosperous "taxi" institution managed by J. R. Wilson, a former livery stable man. His partner in the business is A. P. Rooker, who is president of the company. They have a garage and office at 319 Van Ness avenue, a short distance from the "syndicate's" temporary theatre. At present all the business is done from that place, though the firm contemplates having stands as business grows.

Only Stevens-Duryea cars are used, and the white panel designates them. There are five in operation now and five more have been shipped. The five machines in use were transformed in this city. New bodies were put on and meters attached. They are very handsome cars, and apparently give very satisfactory service. The new ones on the way were transformed in the Fast.

The company has issued a very pretty and unique folder, which is one of the latest pieces of taxicab literature to be mailed throughout the city. It gives a program of the Portola festival, a concise history

of Don Gaspar, discoverer of San Francisco Bay, and has a poem on the fête. It is backed with the Portola colors, and gives rates and other information about taxicabs. This company supplies oil free to drivers, but charges them 15 cents a gallon for gasoline.

#### THE TAXI COMPANY.

with space in the Pioneer Garage, 911 Golden Gate avenue, one of the most pretentious garages at present in this city. operates six Chalmers-Detroit cars. It has no outside stand. A blue panel enables patrons of the company to distinguish its vehicles from the many others about the streets. It is a local company, with officers and directors as follows: Rov M. Pike, president and general manager; J. M. Hotchkiss, J. K. Armsby, H. D. Connick and Anson Herrick.

#### PALACE AUTO COMPANY.

The only company that has its main office downtown and separate from its garage is the Palace Auto Company. Its office is at 105 O'Farrell street, in the very centre of the retail, theatre and café district. Here it has one station. It has another in front of the Orpheum, one in front of D. Samuels' big dry goods house, at Stockton and O'Farrell streets, where many fashionable women shop, and a fourth in front of the Bismarck Café, the big, first class restaurant of Market street. Its garage is at McAllister and Gough streets.

The Palace Company has four cars of its own and it makes use of from four to five belonging to others that it calls on during its busier hours. The machines it has in its own garage are the Thomas. Besides cabs, the company also has some Thomas limousines, which it hires at the rate of \$4 per hour and \$2 per half hour. With the limousine type a taximeter is dispensed with, as a good portion of the people riding in cars prefer something that does not carry a rent sign in front. These limousines all carry speedometers and odometers, by which a record may be kept of the mileage, in case it is wished to charge exact taxicab rates.

The Palace Company expects to increase the number of its cars by half a dozen before winter. It has not decided what make the new ones will be. Both gasoline and oil are supplied free to its drivers.

All the local taxicab companies make repairs to the machines at their own garages. Pneumatic tires are used on all the taxicabs here. The Renault people tried the use of solid tires on theirs, but Manager Beal says he found the machines were jolted too much, and pneumatics are used exclusively now.

The compensation of drivers is uniform. They are given 20 per cent. of the money received and procure oil and gasoline on the basis already stated. The consensus of opinion among the men in the business is that a great deal of the success in its depends upon the employment of capable, intelligent and polite drivers, and effort is made by all of them to weed out all others While the garages of the taxicab companies are large and adequate, the business is so new that no elaborate special ones

have yet been constructed.

#### ADVERTISING.

The taxicab companies are heavy advertisers, both in the daily newspapers and on the dead walls of the city. Display "ads" in the public press and flaring posters on the fences keep the people reminded that there are such things as taxicabs, and advise them to "get the habit." The education of the people to the use of the vehicles is looked upon as an important work by the companies, and they are all assisting in it. Cards and folders are mailed at intervals to the addresses in the directory, so there is not a resident of the city who has not had information about taxicabs brought to him in some manner.

"And there is plenty of room for more work in this line," said the manager of one of the companies. "The people are learning fast, and new ones are making use of the vehicles every day, but you'd be surprised at some of those who even vet don't know what a taxicab is. A leading politician, when I told him the other day that I was in the taxicab business, surprised me by asking 'What is a taxicab, anyway?'

#### LEGAL RESTRICTIONS.

The laws that govern taxicabs here are generally those that govern automobiles, and are simple, having most to do with speed, rates and license. Specifically, the hack law covers the taxis, and a new one has just been passed through the efforts of Manager Beal of the Pacific Taximeter Company. All the change it makes is to permit four hack or cab stands to a block, instead of two, which will give the taxicabs a better chance to get in downtown, though, as stated, the hacks are being crowded out and their former stands become available gradually. This ordinance goes into effect October 15. At the head of the police committee of the supervisors, before which the draft of the ordinance had to go for consideration, was a union labor man, who had aspirations for the mayoralty. It was apparent that any further privileges given taxicabs would be detrimental to hackmen. The committee reported adversely upon the measure, but it was passed anyway by the board and signed by the mayor.

#### APPORTIONMENT OF STANDS.

Now comes the question of the apportionment of stands among the taxicab companies, and there is likely to be a pretty row over it. The law provides that the applicant must secure the signature of the owner of the property or the business concern in front of which he wishes to stand. and present it with his petition to the hack inspector, who recommends to the mayor, the latter issuing the privilege. Beal, with alertness, signed up all the desirable locations before the ordinance was even passed and put the applications in the hands of the hack inspector. He claims the right to the stands by priority, but the other companies say this amounts to nothing, and that after the law becomes effective they will expect to get their share.

It is a fact, though, that now by far the greater part of the business is done directly from the offices, and some of the owners expect that this condition will continue.

The companies all get business out of the big hotels. "Taxis" are summoned from the various companies by 'phone when there is none in sight.

#### EFFECT ON HACKS.

Gradually since the advent of the taxicab the hacks have decreased on the streets. Familiar characters who had driven fares for years in San Francisco, and had become features of its night life, have taken to other lines, though some, who have been thrifty, have acquired motor cars of their own, and are moving along with the tide of transportation progress. One of these, known for years to every nighthawk in San Francisco, has blossomed out with two limousines and his horses are probably doing duty on some ranch.

That the shabby, jolting hack, with its wheezy, jaded horses, should be brushed from the streets by the smooth running, spick and span motor cab is natural.

At the fashionable livery stables, where wealthy persons hire first class equipages, either for pleasure riding or shopping, the taxicab's advent is being felt-even more keenly than that of the automobile. The "taxis" are being utilized more extensively all the time by shoppers and women making their calls. The hacking companies that used to have offices at the big hotels are also suffering. The short hauls of the regulation automobiles are being cut into heavily.

There is one branch of the hack service that is left to the horse drawn vehicles, and that is the funeral business. On this some of the livery firms depend largely to hold out against the encroachment of the taxicabs, which they feel sure can never compete in this line of work.

The license upon taxicabs is that upon all passenger vehicles, viz., \$10 a year. The speed rate is 12 miles inside the city fire limits and 15 outside. There is a State license tax of \$2 a year. Under this law every machine must be registered with the Secretary of State, and is given a large number tag, which must be displayed at all times. Night lights are required by the city ordinance.

#### IN OAKLAND.

In Oakland, across the bay, a city of 200,000 population, privately owned taxicabs are run. Oakland has little of the night life of San Francisco, however, or the day bustle, for, while a prosperous and growing city, it is largely the sleeping place of San Francisco. It has beautiful roads for pleasure riding, though, and as it is a splendid automobile town generally the taxicab will probably get a strong foothold there. Taxicabs from this side do much business between the two cities. The passengers pay the ferriage, which is 75 cents for the machine and 10 cents for each passenger.

While San Francisco has 450,000 population or more, is essentially a motoring town, and is adding both population and buildings with a rush, it is almost safe to say that with the companies already in the field, their present equipment and the large number of taxicabs they contemplate adding, the business is about up to its capacity, though time can best determine this. The old night life of the town is far from being back at its fullest, but it is coming back all the time. This will add greatly to the business in the future. Then the people grow more used to the machines every day, and this causes the business to grow.

In a section where the automobile has won such tremendous favor the taxicab must come in for its share of the honors. The encroachment of motor vehicles on the peninsula of San Francisco was amusingly illustrated the other day during a sitting of the State Board of Equalization for the purpose of looking into county assessments. San Mateo adjoins San Francisco County, and has fine motoring roads. A member of the board who hails from one of the mountainous counties where burros and airships are the best means of transportation asked the San Mateo assessor why it was that fast horses, once forming a big item in the county's roll, had been almost eliminated.

"The automobile has run over them," was the assessor's laconic reply.

#### Autos for Indianapolis Board of Health.

The Indianapolis Board of Health has asked the city council for an appropriation of \$3,500 for the purchase of two runabouts, which are to be used by the city dairy inspectors. All dairies in Indiana supplying milk for Indianapolis consumption are inspected regularly by the city inspectors. Heretofore the work has been done with the aid of electric railway lines and horse drawn vehicles. A series of demonstrations with automobiles has shown three times as much work can be accomplished with such vehicles.

# Manila to Have Motor Fire Engines.

It is reported from Indianapolis that the fire department at Manila, P. I., is preparing to install automobile fire engines. C. F. Samuelson, assistant chief of the Manila Fire Department, was in Indianapolis a few days ago visiting a company that manufactures such engines, but left without placing an order, expecting to visit several factories before reaching a decision. The Manila department has been built up from practically nothing during the last ten years, and now has seventeen fire companies.

#### Commercial Notes.

John Swelander, Isanti, Minn., has established a motor livery business.

The Farmers Supply Company, of Wahpeton, N. Dak., will conduct a motor livery business.

A taxicab service with two Durocars is to be started in Pasadena, Cal., at an early date. The headquurters for the service will be at the Fair Oaks Garage.

C. H. Troyer, chief of police of Duluth, Minn., has made the suggestion that a motor ambulance be provided by the city and stationed at police headquarters.

W. E. Graham, who conducted a motor stage line from Porterville, Cal., to the California Hot Springs for a short time, has discontinued the service owing to the bad condition of the roads.

An automobile service has recently been established by Smith Brothers between Beaver City and Milford, Utah. The route is 32 miles long, and passes through Minersville, Adamsville and Greenville.

One of the Olds delivery wagons which had been used for carrying the mail in Detroit for the past three years has been replaced by a 40 horse power Oldsmobile. The other two cars will be similarly superseded in a short time.

The Appleton, Milwaukee, Chicago & St. Paul Transfer Company will operate an automobile transfer line between Appleton, Wis.; Seymour, a neighboring city, and other towns in the vicinity. Both passengers and freight will be carried.

Louis Blair, of Clearspring, Md., has bought a twelve passenger motor bus and will establish an automobile line between Hagerstown and Clearspring. Mr. Blair has been operating a passenger and freight line with horse vehicles for some years.

The Motor Transfer Company has inaugurated a taxicab service in Fort Wayne, Ind., having a stand in front of the Anthony Hotel. Two cars have been received and two more are to come. The rates are 30 cents for the first half mile and 10 cents for each quarter mile thereafter.

The Jackson City Auto Stage Company, Jackson, Amador County, Cal., which a short time ago established a motor stage service between Jackson and Stockton with two White steamers, has discontinued the service, and is now operating all its machines in the transient business.

Charles M. Deches & Brother, wholesale and retail grocers of the Oranges and adjacent towns, have recently put in service a 3,000 pound truck, made by the Autocar Company, Ardmore, Pa., for use between their warehouses and branch stores. It does the work of a number of horse teams, and in quicker time.

The Columbia Taxicab Company, of St. Louis, has secured the garage of the Bagnell Automobile Company, which will be suitably altered to fit it for the taxicab business. The Columbia Company will shortly have in operation forty Thomas cabs, which number will be increased later. The directors of the company, which was incorporated

only recently, are L. Wade Childress, Frank C. Rand, Robert H. Holmes, Marcus I. Brock and Frederick W. Thomas, the last two of Buffalo, N. Y.

The Nevada Auto Company, which conducts an automobile service between Searchlight, Nipton and Nelson, Nev., has recently added to its equipment a 40 horse power double chain driven Crawford car, and has now four machines in constant service.

The stockholders of the Monroe and Cincinnati Auto Bus Company at a recent meeting in Monroe decided to wind up the company's affairs. The company was organized to run a motor bus line between Cincinnati and Monroe in competition with the Big Four Railroad, but soon found that there was very little chance for its success.

An automobile delivery and motorcycle messenger service has been established at Indianapolis by the Retailers Motorcycle Service, which has just been organized and incorporated. The company has purchased a motor truck, a buckboard and three motorcycles, which will be increased as the demand requires. The concern will make a specialty of deliveries for department stores and other business houses, and in delivering messages from hotels.

# Gyroscope to Be Manufactured in Adrian.

It is reported that the Blomstrom Manufacturing Company have sold the patents for the Gyroscope car to the Page Company, of Adrian, Mich., and that the manufacture of the car will be taken up on a large scale in Adrian in the near future. The Page Woven Wire Fence Company and its allied concerns are old established manufacturers, and form the principal business interests of Adrian. They have been interested in the automobile business for some time, and have done a considerable amount of experimental work, having built a number of models fitted with air cooled motors, two cycle motors, etc.

A New Detroit Automobile Company.

The Krit Motor Car Company has been organized in Detroit to manufacture cars from the designs of Kenneth Crittenden. The capital stock is given as \$100,000, of which \$50,000 is subscribed for and \$23,000 invested in models, specifications, machinery and completed cars. The incorporators are B. C. Laughlin, W. S. Piggins, Claude S. Briggs, Kenneth Crittenden and C. W. Whitson, each of whom holds 100 shares of \$100 each. It is stated that four cylinder cars will be manufactured.

#### Carriage Firm Gives Up Auto Manufacture.

The Columbia Carriage Company, Hamilton, Ohio, who made twenty-five solid tire motor buggies, have decided to abandon the manufacture of motor cars, and will confine themselves to horse drawn vehicles hereafter.

### Complains of Treatment at Garages While on a Tour.

Editor Horseless Age:

Will you not take up a matter that concerns most motorists, namely, the brazen thievery that goes on in practically every garage in this part of the United States?

It has been my experience every time I turn my car in for either one night or more, when touring, to have sundry small things 'taken from it, and the last time, when in a large New York garage in the heart of the city, three articles amounting to over \$15 were taken, and absolutely no satisfaction was given me.

It is absurd to expect an owner to strip his car every time he puts it in a garage, and the fact that he pays for the care of the car at so much per diem should include its contents. I have found my tool chest broken open and small tools taken, a pair of gloves or goggles, tobacco, Scotch whiskey, a pocket pistol, blue books, robes, dusters, an umbrella—in fact something disappears at every stop I make.

Now, I take particular pains to tour very fully equipped for every comfort, and in making a one or two nights stop en tour I do not expect to pile out everything that has been closely packed away in the car for possible emergencies, change of weather, etc.

Garages put up a large sign that they will not be held responsible for things left in cars, and they thereby put a premium on the dishonesty of not only their own employees but of the chauffeurs who hang around the place.

That these chauffeurs take especial pleasure in overhauling a car that is run by the owner I well know, and they always empty my tobacco box and whiskey flask, and clean up any luncheon that may be in the basket.

It probably will take time to convince people on this side of the continent that there is a class in this country whose means would readily permit their employing a chauffeur, valet or maid, but who prefer to do without their services solely because they wish to do without their society. That such a class does exist, all those who have lived out West know. These people pay for service as they need it, and perhaps pay more in consequence than if they employed and kept on tap servants of their own, but they dislike hangers-on, and therefore do not travel about accompanied by an Irish or French boarding house.

In the West when a man runs his own car into a garage this fact is understood, and the man is judged for what he himself appears to be, but in this part of the country the man who runs his car to a garage is "poor white trash," and treated accordingly, no matter whether he pays liberally for

both storage and cleaning for his machine. And every time he puts his car up in a strange garage it is pilfered.

And let me say, moreover, Mr. Editor, that I have had this experience only in the East; I never lost a cotter pin from my car out West.

No wonder that I am but one of many who come East with the intention of spending my declining years in luxury here, and find I get anything but what I expected, and am returning to the far more comfortable and independent living on the Pacific Coast, just as soon as I can.

A DISGRUNTLED WESTERNER.

#### Automobile Statistics.

Editor Horseless Age:

Will you kindly advise me where I can obtain the following statistics? The approximate number of automobiles now in use, and the approximate number manufactured and sold last year in each of the following countries: The United States, Canada, England, Germany, France, Spain.

R. B. HEAD.

[It is extremely difficult to get accurate statistics of this nature. The following figures have been obtained from various sources, and are largely estimates based upon registrations or assessment records in previous years, except in the case of Germany, which takes a census of automobiles at the beginning of each year:

ESTIMATED HUM	BER OF	CARS	IN USE	ΑT	PRESENT.
United States					200,000
Canada					
England					100,000
Germany					18,500
France					40,000
Spain				• • • •	3,000

As to the number of cars manufactured in the different countries last year there are absolutely no reliable statistics on this point. The production in this country has been estimated at about 80,000. The production in Germany can be calculated fairly closely by comparing the number of cars in the country at the beginning and end of the year, taking account of the imports and exports, and making a fair allowance for retirement of old cars. On this basis we come to the result that about 7,000 cars were built in that country last year. For the other countries there are no figures available that we know of.—Ed.]

### Power Tire Pumps.

Editor Horseless Age:

I have been in the automobile game and a subscriber to your journal for the past six years. In that time I have progressed from one cylinder to six, from single tubed tires to a very satisfactory quick detachable type, from dry cells to a thoroughly reliable magneto as current source. I have been relieved of the labor and risk of cranking by a thoroughly reliable self starter. In fact I have seen the automobile develop and improve along every line except one. My tire pump is built upon the same plan as the one I used in 1903, slightly stronger perhaps, but requiring just as much sweat

to inflate a tire. In addition to the labor of operating the hand pump it is humiliating and aggravating to have 48 horse power stand idle beside me while I struggle with a relic of the earliest bicycle days.

Will you kindly advise me if there is a reliable air pump which I can attach to my motor for tire inflation? I have seen several advertised in your columns, but the cuts were so small that I was unable to secure from them any idea of the apparatus.

It seems to me there ought to be a large sale for a proper air pump suited for attachment to the various cars, and backed by a vigorous advertising campaign.

R. R. Lewis.

[We do not believe that there is the least necessity at the present time for pumping tires up by hand. Motor driven tire pumps are advertised in our columns regularly. Some of these have been on the market for a considerable number of years, and we have never heard a complaint about them.

—ED.]

# Starting Six Cylinder Motors on Compressed Air.

Editor Horseless Age:

As an old subscriber to your valued paper, I would like to ask the following question through your columns:

If a six cylinder, four cycle engine were provided with balanced piston inlet valves, auxiliary exhaust ports, and a check valve in the inlet pipe above the carburetor, would the engine always start upon compressed air being admitted to the inlet pipe or manifold? That is, would one or more inlet valves be open at any position the engine might stop, and would you consider it good practice? ENQUIRER.

[One inlet valve would always be open, and sometimes two, and the engine would start without fail if there were pressure in the tank. The inlet valves remain open during practically one-half revolution of the crank shaft. The periods of the six inlet valve openings therefore correspond to three revolutions of the crank shaft. It follows from this directly that half the time only one inlet valve is open, and half the time two are open.

The chief objection to your proposed design would undoubtedly be the check valve in the inlet pipe above the carburetor, as this corresponds to an automatic inlet valve, which has several disadvantages, among which may be mentioned the tendency to gum to the seat and that to reduce the volume of charge under certain conditions of running. It would probably be advantageous to use the checks in the air piping, and use the conventional valve system.

—ED.]

#### Safety Steering Gears.

Editor Horseless Age:

Your editorial on "Steering Gear Accidents" is aimed at the right idea, but seems to me to go about it wrong. The time is slowly arriving when excess weight and

duplicate parts will not be tolerated in an auto. The users are beginning to see that much weight and complication means much expense and worry. Sooner or later the emergency brake will go. Users are learning by experience that in an emergency they cannot think, and have no time to do anything other than they have by much practice learned to do without thinking. Only last month I was in a rig which stopped against a telephone pole because the driver lost his head on finding a team headed toward him on the wrong side of the road as he turned a bad corner. A single movement of the brake, throttle or clutch lever to reverse would have stopped the rig, but the driver simply could not think, and the possession of an anchor or a dozen emergency brakes would not have helped him. So with a broken steering gear. The rig is in the ditch and the damage done before the driver could awake to the fact that the car did not respond to the steering wheel and grab another wheel

The best thing to do is to make the parts so they will not break in the first place, and so will not immediately cease their functions if they do break in the second place. You will understand what I mean by this if you remember that a cycle is not unsteerable if its handle bar comes loose, A properly hung cycle will go right ahead without a bar, and can be ridden over fairly large obstacles like a brick "hands off." Provide autos with similar steerings, and they will run with no strain on the steering parts in the first place, and will continue with reasonable certainty if the steering arms and links are broken in the second place.

Worm devices are used to take the strain and ierk off the driver's hands. This does not lessen the jerk on the arms and links of the rig, however, and the very fact that they are held rigidly increases the likelihood of breakage. The willow and oak comparison holds good here, as in many other places. The irreversible steering gets strains that the steering free to yield does not. The steering pivots can be placed in the plane of the wheels, as in a cycle, or inclined at the side, as has been done in Duryea vehicles since the beginning, and then there is practically no strain on the arms and links. This can be readily proven by dropping off the tie rod, which runs parallel to the axle, and the free wheel will continue on its course just as if steered. I have proven this more than once. Have crossed car tracks paved between with cobbles; have climbed short hills and made turns during the climb, and have driven for considerable distance on fair roads with one wheel free in this manner. CHAS. E. DURYEA.

The Motor Racing Association, of New York City, will hold another twenty-four hour race on the Brighton Beach track September 24-25, coincident with the opening of the Hudson-Fulton celebrations. The race will start at 6 o'clock on Friday evening, so it will not interfere with the night pageant on the Hudson on Saturday.

#### Automobiles in Spain.

The use of automobiles is restricted by the high price of gasoline and by the poor roads. Owing to the almost prohibitive duty on gasoline, it costs 49 cents per gallon there. Nevertheless automobiling is making progress in Spain, and while the use of the machine is confined to the wealthy few, more machines are being manufactured in Spain and imported from abroad every year. The president of a leading automobile club estimated the cars in use in September, 1008, to be as follows: Madrid and district, 500: Barcelona and district, 600: Guipuzcoa and Sebastian, 300; Vizcaya (Bilbao), 200; Palma de Mallorca, 300; Seville and district, 100; all other parts of Spain, 1,000; total, 3,000.

There is only one Spanish concern engaged in the manufacture of automobiles. This plant, founded in 1902, has grown steadily in importance. It turns out cars of various horse power, the most popular model being the 20 horse power. In addition to a steadily increasing home market, its machines are exported to Argentina, Mexico and Porto Rico. A French company has a branch factory at Vitoria, near San Sebastian.

Imports of automobiles, while not very considerable, are important when compared with the total number of machines in Spain. The total in 1907 was 227 cars, valued at \$248,774, of which only 4 cars, worth \$3,460, came from the United States. France furnished 151 cars, valued at \$170,059.

The average price of a first class 20 to 24 horse power, four cylinder gasoline car in Barcelona, with open side entrance body, is from \$3,100 to \$3,175; second grade four cylinder French cars, of well known make, \$300 to \$400 cheaper. Cars in use in Spain range from 16 to 40 horse power, the most popular car being the 16 to 20 or 20 to 24 horse power. Steam cars have been tried but given up. Steam cars and electric runabouts ought, however, to have a decided advantage in Spain on account of the high price of gasoline.

#### OPENING FOR AMERICAN AUTOMOBILES.

A local automobile man states it to be his opinion that an excellent market can be developed in Spain for American makes. This opinion, the result of careful comparison between American and European cars, is based upon difference of price in favor of American cars, as well as their greater adaptability to Spanish conditions. American cars, being made very strong and high swung, run admirably along the Spanish roads. Attention is again called to the opportunities for American supplies, tires, lamps, tools, etc.

If American makers can put their cars in Spain at prices which permit competition with foreign, particularly French, cars, their superiority for rough work ought to give them an appreciable advantage. In spite of the great vogue enjoyed by French cars, the Spanish buyer would undoubtedly receive American cars favorably when once

convinced of their superiority for his own purpose. But it must be steadily borne in mind that to convince the Spanish buyer of the advantages of our machines catalogues and price lists will not suffice. He must be able to see the car, examine it carefully, and even take trial spins before he will consider the matter seriously. To deal with prospective customers agencies must be established and equipped with good lines of machines and supplies, where cars can be submitted to a thorough examination and comparison with competing makes. All the leading French manufacturers have such agencies at Barcelona, in addition to some Italian and German houses. A little advertising of the right sort would undoubtedly be effective. In a recent contest -La Copa de Cataluna-for voiturettes, the first prize was won by a French car. The race aroused tremendous enthusiasm, and the presence of a good American car would have done much to attract attention. The Copa de Cataluna is an annual event, being held every spring.

Very few automobile drays are seen in Spain, carts drawn by strings of mules or a pair of oxen being commoner sights, even in Madrid and Barcelona. The Madrid postal authorities have an automobile service to and from the railway stations. Imports of automobile drays and delivery wagons in 1907 were valued at \$27,391.—Consular Report.

#### Book Review.

Principal Automobile Routes of the United States and Canada, 1910. By H. Sargent Michaels. Published by the Henneberry Company, 554 Wabash avenue, Chicago. Price, \$1.25.

The book contains brief route descriptions of sixty touring routes, most of which start from Chicago. It gives the distances to all points en route, and a list of hotels arranged by cities alphabetically. It is accompanied by two loose maps, one of Chicago and its suburbs, and the other of a part of Illinois and Wisconsin.

#### Milwaukee Municipal Garage.

Milwaukee, Wis., is considering the establishment of a municipal garage to care for the eight automobiles now owned by the fire and police departments of the city. It was found very expensive to keep the machines in various different garages. By erecting its own garage the city hopes to reduce this expense, as well as to insure their more adequate repair, and to prevent machines being used for other than strictly municipal purposes. A site has already been purchased by the city. City Comptroller A. M. Gawain and a number of aldermen favor the plan.

According to a recent report by the Austrian Consul at Amsterdam, Holland offers a good opening for the importation of motor cars. In 1908 a brisk business was done in the lighter type of motor cars.

# New Connecticut Law Now in Effect.

The amended automobile law passed by the Connecticut Legislature during the last session went into effect on September 1. Following is an abstract of the law:

All registrations are now annual. Owners' registrations expire December 31 at midnight and drivers' registrations the last day of February at midnight. Upon the sale of a car its registration expires, but the vendee may file a new application, and upon the payment of a fee of \$2 may have registered another car in his name for the remainder of the calendar year, provided the horse power of the new car is not greater than that of the old one; if it is greater, he must pay in addition to such fee the difference between the fee paid by him for the motor vehicle sold or transferred by him and the fee for the registration of the motor vehicle of the higher horse power.

All operators of motor vehicles and motorcycles must obtain a license annually. The fee for an operator's license is \$2. Licenses must at all times be carried by the licensee when he is operating a motor vehicle or a motorcycle. Operator means a person who has obtained a license to operate a motor vehicle or a motorcycle.

Non-residents who have complied with the laws of the State of their residence may use the highways of Connecticut not exceeding ten days in any one year without complying with the provisions of this act relative to the registration of motor vehicles and the licensing of operators, but must cause to be displayed on their motor vehicle the distinguishing number or mark of the State within which they reside, and said number or mark shall be displayed upon two plates substantially as provided in Section 4 of this act; provided, however, that if any non-resident be convicted of violating any provision of Sections 11, 12, 18 or 10 hereof (relating to speeding, escaping after accidents and refusal to show license to police officers), he shall thereafter be subject to and required to comply with all of the provisions of this act.

No person shall operate a motor vehicle on the public highways of this State recklessly or at a rate of speed greater than is reasonable and proper, having regard to the width, traffic and use of the highway, or so as to endanger the property or the life or limb of any person.

Each machine is required to bear a different number and be registered separately. One set of official markers are furnished annually without charge. Only official markers can be used, and must be obtained of the Secretary of the State; provided, that in case of the loss or mutilation of a marker, the owner or person controlling a motor vehicle must immediately place a temporary plate bearing his registration number on such motor vehicle and within twenty-four hours after such loss or mutilation notify the Secretary and apply for a new set of number plates, which will be furnished on the payment of \$1. In case of a loss of certificate or license, duplicates may be secured from the Secretary on payment of 50 cents for each duplicate of license or registration.

Manufacturers, dealers and liverymen will be required to use special markers, furnished by the Secretary, six sets of which will be furnished with the certificate of registration, annually, and one pair of plates for individual owners, upon application therefor, without charge.

The registration certificate of each machine must be conveniently kept in the same. Each operator must carry his license so it can be shown when required.

All applications for registration and license must be made on blanks furnished by the Secretary, the writing must be legible and signature plainly written. All blanks must be filled in and all questions answered. All registration cards must be returned to Secretary's office unmutilated, as they are used in a filing case as a card index.

Upon the sale or transfer of ownership, any person in whose name such motor vehicle or motorcycle is registered must return to the Secretary's office the old certificate, together with the name and address of the new owner. All operators must indorse their signatures on the space provided immediately upon the receipt of such license, and the license will not be valid until so indorsed.

#### LICENSE FEES.

The fees for annual registration of cars are as follows: \$1 for each motorcycle, regardless of horse power; \$5 for each commercial motor vehicle, regardless of horse power: \$10 for each motor vehicle owned or controlled by a liveryman; 60 cents per horse power for every other motor vehicle of 25 horse power or more; 50 cents per horse power for every other motor vehicle of less than 25 horse power. The horse power must be based on the A. L. A. M. rating formula in the case of internal combustion engines, and in the case of steam and electric cars must be based on the horse power as advertised by the maker, and in the case of two ratings the registration must be based on the higher rating. A pro rata reduction in fees is allowed on applications for registration filed after the 1st day in June in any year, and the Secretary of State has had tables prepared showing at a glance the amount of the fees to be paid for cars of any horse power up to 24, in any calendar month from June to December, inclusive, and for cars of any horse power from 25 to 80, in any calendar month from June to December, inclusive, respect-

#### Recent Decisions.

LIMITS OF PERIOD OF GRACE.

Massachusetts statutes authorized a nonresident who has complied with the laws of his State to use his automobile in Massachusetts fifteen days without a license. It was held that a trip into Connecticut and Vermont and time lost in the repair shop were not to be excluded in estimating the time, and that where the owner of an automobile had exceeded his privilege in operating his car more than fifteen days without a license, he was a trespasser on the highway, and in an action against a street railway company for injuries he was only entitled to the rights of a trespasser, and a verdict for the railway company was properly directed.—Dudley v. Northampton St. Rv. Co., 80 N. E. 25.

#### BREACH OF WARRANTY.

An action was brought in the Supreme Court against the manufacturer and the sales agent for damages for breach of warranty of an automobile. Previously an action was brought in the Municipal Court by the agent for repairs, in which action the purchaser set up damages on the breach of warranty as a counter claim. It was held that he was entitled to a trial of his counter claim notwithstanding the action in the Supreme Court, as the parties were not the same.—Robert Thompson Co. v. Levis, 117 N. Y. Supp. 1057.

#### AGENT'S RIGHTS.

Where an agency was established by an automobile manufacturing company, and the agent agreed to take three automobiles, and to have a discount of 20 per cent., and to make a deposit of \$250 on each on ordering the cars, and after he received one car the company rescinded the contract and established another agency, it was held that the agent was entitled to recover the deposits made on the other two cars not furnished.—Drake v. White Sewing Machine Co., 118 N. Y. Supp. 178.

### Coroner's Verdicts in Race Fatalities.

John J. Blackwell, coroner of Marion County (Indianapolis), in his report on the death of Claude S. Kellum, the mechanic who rode with Chas. Merz on the Indianapolis track, says in part as follows:

"I find by the inquest that the cause of the accident was the bursting of a tire on the automobile driven by Charles Merz.

"I find that the cause of the bursting of the tire that caused the death of C. S. Kellum was the unfinished track, and that the Indianapolis Speedway Company put on the races before the track was completed and safe.

"I firmly believe that the Indianapolis Motor Speedway Company should have used more precaution, and not have allowed the races to go on until the track was in good condition."

Coroner Brewer, of Brooklyn, who made an inquest into the deaths of Leonard Cole and Laurente Grosse, mechanic and driver, respectively, of the Stearns car that collided with one of the Acmes on the Brighton Beach track on August 27, states in his verdict that "the men came to their death through a collision between the Stearns and Acme machines, due to the recklessness of the Stearns crew in trying to pass the Acme near a turn"

### Joy Riding Epidemic in Detroit.

During the past few weeks a great number of autos have been stolen in Detroit, mostly for joy riding purposes. Last week four youths were sentenced in the Justice Court to pay fines of \$100 each, and serve ninety days in the house of correction, for taking an auto which they ran out of town and badly damaged in a nearby village. This was the maximum sentence under the old law, but on September I a new statute went into effect which makes the taking of a machine without the owner's consent a much more serious offense. It remains to be seen if the more severe penalty will reduce the number of offenses.

### Wisconsin Gasoline Inspection Law Defeated.

By dismissing the suit brought against Thomas B. Jeffery & Co., of Kenosha, Wis., for refusing to pay for the inspection of seventy-two barrels of gasoline as provided for under the new oil inspection law, Judge Clifford E. Randall took the first step in declaring the statute unconstitutional. The Jeffery Company brought the test case in the interest of all automobile owners. The State will probably carry the case to the Supreme Court.

#### Legal Notes.

By an ordinance which has been given its second reading by the Columbus (Ohio) City Council, quantities of gasoline cannot be stored nearer than 50 feet to any structure. The ordinance will likely be enacted and will change the method of storing gasoline on the part of several Columbus garages.

Alderman Dunn, of Chicago, has drawn up an ordinance which provides for the examination and licensing of all drivers of public automobiles. The ordinance is said to have the support of Alderman Arthur B. McCoit, president of the Chicago Taxicab Company. It is at present in the hands of Howard W. Hayes, assistant corporation counsel.

The Turner Brass Works, Sycamore, Ill., have secured a temporary injunction against the Vanguard Manufacturing Company, restraining them from manufacturing, selling or using spring bumpers infringing the Harroun patent, which is owned by the Turner Brass Works. We understand that nine other suits are now pending against alleged infringers of this patent.

The police of Boston are strictly enforcing the provision of the new State law requiring the blowing of the horn before

coming to crossroads or intersecting streets. Officers are stationed on Massachusetts avenue, between Boylston street and the Harvard Bridge, and at Columbus avenue and West Newton street. No warnings are given, but all who fail to blow their horn are arrested.

#### Ordering Repair Parts.

By H. S. WHEELER,

"Did you ever experience difficulty in obtaining the correct repair part for your car?"

"Yes."

"Did you ever think that the factory repair department was not 'up to snuff'?"

"Yes."

"Did you ever stop to think that any concern's satisfied customers are its best advertisers, and that it would consequently be far from sane business policy to give customers anything but the best of service from this department?"

"Yes, but--"

"I know; but did you ever stop to think when incorrect parts or parts that did not fit were sent you that perhaps you were just a little to blame?"

The repair and parts order department of any firm engaged in a manufacturing business of the nature of the automobile business is the one thing acting as a stepping stone or as a stumbling block, as the case may be, in the stream between manufacturer and consumer. It must anticipate possible parts breakages and the wear to which all machines are subject, and must furnish at a moment's notice parts necessary to repair a car produced ten years ago, as well as for a car built yesterday.

Let us look at the quantities of stock which must be carried. For a product of 4,000 cars made in four different models a certain factory's "parts price list" shows that approximately 5,600 parts can be furnished. Actually this quantity will run to about 6,000.

Various elaborate systems must be devised for maintaining such a stock, composed of parts as different as wooden seat bottoms and lubricating oil or front axles, and "internal hub brake operating lever latch spoon bolt nuts." Each piece of this stock must be accounted for at all times, and it must be known just how long a certain number of each part should last, how great a quantity should be ordered at a time, and how long after ordering before the goods will be available for shipment.

Granting that the stock is maintained in an absolutely satisfactory manner, we come to the proposition of filling parts orders. Let us take a concrete case.

You skid on a wet pavement and break a wheel; telephone the garage to get the "darn" car and fix it up, and go on home to your dinner. That evening the garage wires the factory: "Express right front wheel painted Smith's car." They don't stop to think that wheels are not right and left.

In the morning you get up early, so you will get down to business via street car on time, and about noon, when you've about decided to go out to the Country Club for a round of golf you remember your car is not running, and 'phone the garage what the news is regarding the wheel.

A wire was received some time ago from the factory reading "Wire relative front wheel; give us car number quick.' Seven men in your city named Smith have cars of the same make as yours, and, anyway, you didn't take the trouble to write the factory for future reference that you owned car No. 10,787.

Of course, the garage people don't want you to know they forgot to wire in the car number when ordering, so you are informed that no news has been received.

Fine service you are getting from the factory, aren't you? You call your stenographer in and tell her to take this wire: "Rush wheel for car quick. Answer." The girl sends the wire, signing, it as usual, "Easton Real Estate Company"—not Smith—and, of course, you do not think to include in your wire that the Empire Garage ordered the wheel.

Not wanting to take the interurban out to the Country Club, you decide to stay in the office, and about 3 o'clock you, or rather the Easton Real Estate Company, get a wire: "No wheel on order for you. Send full information."

You sit down and dictate a letter that makes your stenographer blush, but incidentally mention the name of the garage which ordered the wheel. When the factory receives your letter everything is perfectly clear to them. They write or wire you, and wire the garage (which in the meantime has wired in the car number): "Information satisfactory; wheel goes American Express today."

After waiting patiently or impatiently for the express to come, the wheel finally arrives in good condition.

If you had looked over your parts price list, and had wired for "one culvert," you would have received it by first express.

Moral: Order repair parts correctly and you will receive correct parts.

# To Build Double Power Cars in Philadelphia.

The Standard Gas and Electric Power Company is being organized in Philadelphia to manufacture touring cars and trucks equipped with a combination gasoline and electric power systems. The touring car is to be fitted with a 35 horse power motor and the truck is to be of 3 tons capacity. The company also plans to build a track motor car for use in interurban service on steam railroads. A special feature of the automobiles is that the changes of speed are effected by means of push buttons instead of a gear lever. Samuel S. Eveland, president of the Standard Roller Bearing Company, is largely interested in the new company.

#### The Lowell Races.

The Lowell (Mass.) Automobile Carnival started on Monday, Labor Day, with the so called national small car sweepstakes. This consisted essentially of three races held over the same course at the same time. These races were held over a circuit 10.6 miles in length, known as the Merrimac Valley course. The three races were as follows:

For the Vesper Trophy, open to cars of 301-450 cubic inches cylinder capacity, with a minimum weight of 2,100 pounds; twenty rounds, 212 miles.

For the Yorick Club Trophy, open to cars of 231-300 cubic inches cylinder capacity, with a minimum weight of 1,800 pounds; fifteen rounds, 150 miles.

For the Merrimac Valley Trophy, open to cars of 161-230 cubic inches cylinder capacity, with a minimum weight of 1,500 pounds; twelve rounds, 127.2 miles.

The Vesper Trophy was won by Robert Burman (Buick), who covered the 212 miles in 229 minutes 8 seconds. He made his fastest lap at the rate of over a mile a minute. The Yorick Club Trophy was won by Louis Chevrolet (Buick), in 2:56:17, and the Merrimac Valley Trophy was won by "Billy" Knipper (Chalmers-Detroit), who covered the 127.2 miles in 2:28:43. Knipper was protested by Arthur See, driver of a Maxwell, which came in second, on the ground that he had the hood on his car open during the race, but the protest was disallowed.

The race was attended by large crowds, and passed off without fatal accidents. One car ran off the course onto an embankment and turned over; another crashed into a telegraph pole and several people were injured.

### Following are the summaries:

- onowing are the summaries.	
CLASS 2-212 MILES.	
Finish. Driver and Car. H. P.	Time.
1-Robert Burman, Buick 30	3:49:08

* Protested.	•

On Tuesday a series of 1 mile straightaway speed trials were held over a specially laid out stretch on the Merrimac Valley course, and a new record for the mile with standing start was established by Barney Oldfield, driving a Benz racer. His time was 51 1-5 seconds. Oldfield also made an attempt to lower the flying start mile record, but could do no better than

39 9-10 seconds, which is 1½ seconds more than the record time. Walter Christie, who was to have been one of the stars of the day with his front driven racer, was unable to take part in the events, owing to the twisting off of a shaft on his machine early in the day. Lewis Strang, another racing notability entered for the events, also did not appear. Next to Oldfield the best performance during the day was scored by Louis Chevrolet (Buick), who won two firsts, two seconds and one third. The summaries follow:

Class Four—Gasoline Stock Cars, Selling \$1,251 TO \$2,000.

### Special Metallic Mirrors for Headlights.

It will be remembered that one of the lamps fitted with gold plated reflectors which was tested by the R. A. C. in their recent trial of headlamps had its mirror constructed on the Cowper-Coles system, instead of being formed like an ordinary metallic reflector or with a metallic backing behind a glass body. The lamp in question was that entered by the Reflector Syndicate, and had a 22½ candle power

acetylene burner, arranged within the focus of its parabolic mirror. As with the other gold plated reflectors which were entered by other makers, the primary object in the use of gold in lieu of silver is that of softening the light in such a way that it not only ceases to be so dazzling to other road users, but that its penetrating powers through mist and fog are enhanced considerably. A special interest attaches, however, to the Cowper-Coles system itslf, and consequently a few words concerning its object and its nature will be very appropriate now that so much attention is being given to lamps for motor cars.

Originally the endeavor was made in connection with naval searchlights to substitute metallic mirrors for those made of glass, because the older type of mirror was apt to be readily broken by concussion when firing the guns, and because, too, the silvering at the back was very liable to blister off the surface of the glass under the influence of the weather. To that end. the Cowper-Coles electrolytic process was introduced whereby the convex side of a glass former or mold had a thin silver film deposited upon it by chemical means, and the former or mold was then spun in an electrolytic cell so that copper was deposited upon the silver surface. This latter process was continued until the silver film had received a sufficient backing of copper to impart the desired rigidity to the finished mirror, and subsequently the metallic mirror thus built up was separated from the glass mold by being placed in a vessel containing cold water, the temperature of which was gradually raised until the expansion of the copper was sufficient for the purpose. The silver face produced in this manner has as highly polished a surface as glass, and then only needs to be subjected to an after-treatment which will prevent the silver from tarnishing.

An intensely bright beam is projected by this mirror, and so dazzling is the light that it is impossible for those within its area to aim accurately at the projector, while another advantage of the construction is freedom from fracture by concussion or of any great area of distortion even when penetrated by bullets.

A number of mirrors made in the way we have just described have been employed by the War Office, but Mr. Cowper-Coles has more recently introduced a metallic mirror of another kind, which is only partly made by electro-deposition. This type of reflector has a surface composed of alternate bands or rings of gold and silver, for which a more penetrating beam of light is claimed both at night and in foggy weather.

For automobile purposes, of course, a reduction of dazzling effect is of predominating importance, even though penetration at night or in fog is an invaluable feature. Mr. Cowper-Coles has therefore brought out yet another form of glass or metal parabolic mirror coated with a yellow metal for this particular work.—Automotor Journal.

### MINOR MENTION

Raymond M. Owen, of New York, informs us that, rumors to the contrary not-withstanding, his automobile connections are limited to the Reo and Premier.

The Drummond Carriage Company, of Omaha, Neb., are selling out their line of carriages and buggies to make room for an automobile repair business and the manufacture of automobile bodies and tops.

George W. Burnside, R. J. Wells, B. S. Wells and Thomas Fawick have formed a stock company at Sioux Falls, S. Dak., with a capital stock of \$100,000, to manufacture the "Silent Sioux," a two cylinder car.

C. H. Stratton, president of the C. H. Stratton Carriage Company, of Muncie, Ind. is negotiating with the business men of Wabash, Ind. with regard to the location of an automobile factory there. Mr. Stratton has several novelties in the line of convertible automobile bodies.

The Howard Motor Works, of Yonkers, N. Y., will be removed to Athens, N. Y., and reorganized as the Athens Motor Truck Company. Designs are now being gotten out for a 1.000 pound delivery wagon and I ton truck. Operations in the Athens plant will probably begin about the middle of November.

The Holson Motor Patents Company, of Grand Rapids, Mich., which is the parent company exploiting the Holson electric truck construction in which the motors are placed inside the driving wheels, has changed its name to Church Balance Gear Company, Ltd. M. B. Church owns the controlling interest in the company.

The contract for the decoration of the Grand Central Palace, New York, for the Tenth International Automobile Show has been let to Unitt & Wickes. The building is to be transformed into a trellis garden, a scheme which involves a lattice and land-scape effect with myriads of electric lights and huge fire balls to bring out the pictorial scenes and floral designs.

The Jewel Carriage Company, of Carthage, Ohio, point out that, contrary to a statement made in our issue of August 25, they will not turn out a \$1,500 car for 1910, but will continue the manufacture of their touring car at the same price as in 1909, viz., \$2,000. In addition they will turn out five other models, including a runabout, ranging in price from \$1,750 to \$1,000.

In the annual report of the directors of the American Locomotive Company it is stated that the sales of automobiles manufactured by the company have greatly increased, and business in this department was so satisfactory during the past year that a number of the buildings of the Providence plant, which were abandoned after the panic by the locomotive department, have been fitted up for the manufacture of automobiles.

James Fletcher, of Seatonville, Ill., is endeavoring to organize an automobile manufacturing company at Peru, Ill.

In Kearny, Neb., and vicinity eightyseven cars are said to be owned, twentyeight of these being Ramblers, twenty Buicks and fourteen Reos.

H. C. Biddison has purchased the entire interest of W. C. Schoelkopf in the Schoelkopf Manufacturing Company, Madison, Wis., and the name has been changed to the Biddison Manufacturing Company.

Raymond B. Doty, of Cleveland, Ohio, has designed an electric car which will be manufactured by the Cleveland Electric Vehicle Company. We are informed that in a recent test run the car, which is a four passenger machine, ran 133 miles on one charge of the battery.

The Sternberg Manufacturing Company, of Milwaukee, Wis., will remove their plant to West Allis, Wis. A new factory, 200x350 feet in dimensions, will be constructed of brick and concrete. William Sternberg, president of the company, estimates that the new plant will enable the company to turn out 200 motor trucks yearly.

The W. A. Salter Motor Company, is erecting a factory at 1510-1516 Oakland avenue, Centropolis, Kansas City, Mo. The company was organized recently by W. A. Salter, who formerly lived in Cottonwood Falls, Kansas. It will turn out a 40 horse power car with a motor and transmission invented by Mr. Salter.

It is reported from Grand Rapids, Mich., that the Austin Automobile Company, of that city, is to be removed to Toledo, Ohio. J. E. Austin, president of the company, when interviewed in regard to the matter, said that the company had received several offers from other cities, but had not yet decided whether it would accept any of the offers.

General Veraqua, commissioned by the Government of Peru to make a study of North American and European army equipment, recently made a visit to Racine, Wis., to inspect several cars manufactured there, and left an agent, Professor Pimienta, to make a thorough investigation of the durability and hill climbing capabilities of these automobiles.

The Studebaker Automobile Company, of South Bend, Ind., who guarantee their cars for one year, inform us that the total expense to them of the guarantee on 1,571 Studebaker-Garford chassis during the period from March, 1905, to October, 1908, amounted to only \$16,620.18, or \$10.51 per car. They claim to have been more than liberal in making good their guarantee.

The total exports of automobiles from San Francisco during the month of July amounted to thirteen cars, valued at \$21,-283, and parts valued at \$3,127, as compared with twenty-two cars, valued at \$42,732, and parts valued at \$5.806 during the same month the previous year. Of the thirteen

cars exported last July nine were shipped to Hawaii, one to England, one to Canada, one to the Philippines, and one to Japan.

The Hudson Motor Car Company state that they expect to deliver at least 5,000 of their "20s" before March 1.

The Timken Roller Bearing Company, Canton, Ohio, are adding new buildings, increasing their capacity 200 per cent.

Heald's Automobile School, San Francisco, Cal., has been moved from 425 Mc-Allister street to 521 Van Ness avenue.

The G & J Tire Company have established a branch in St. Louis, at 4148 Olive street. in charge of J. P. Trader, formerly manager of the Firestone St. Louis branch.

A. C. Yocum & Co., motor manufacturers, Reading, Pa., will soon move into their new factory at Oakland, a suburb, where they will turn out a three or four cylinder runabout named the Speedwell, at a moderate price.

The Auto Radiator Works have been established at 379' Valencia street, San Francisco, Cal., under the management of Harry H. Pencovic, and will engage in repair work on radiators and other sheet metal parts of automobiles.

The drawing for spaces at the Atlanta Automobile Show will be held at the M. A. A. M. rooms, 7 East Forty-second street, New York, today (Wednesday) at 2 o'clock. L. M. Bradley has been appointed publicity manager for the show.

In our comments on the Glidden tour we gave it as our opinion that solid rubber tires did not permit of maintaining a speed equal to that called for by the schedule. In making this statement we had in mind true solid rubber tires, and not the so called airless tires.

The Sheldon Axle Works Company, of Wilkes-Barre, Pa., who manufacture springs for automobiles on a large scale, are considering the advisability of engaging in the manufacture of other automobile parts, which would necessitate the erection and equipment of a special factory.

The United States Carriage Company, of Columbus, Ohio, has decided to engage in the manufacture of touring cars, runabouts, motor hearses, cabs and ambulances. The concern will manufacture a four cylinder engine, with which the vehicles will be equipped. The new cars will be on the market early next year.

John Harter, of Oceola, Ohio, has invented a sectional steel tire, which is to be fitted over the ordinary pneumatic tire to protect it from injury, and to reduce wear. The whole steel tire consists of sixty-five sections, which are connected together by a pair of flat steel strips. A set of these tires is at present being made by the Carroll Works in Bucyrus, Ohio.

Several automobile dealers and manufacturers of Indianapolis had exhibits at the State Fair held in that city the week of September 10. No special provision was made for automobile exhibits, and the dealers and manufacturers were compelled to use tents. There has been agitation for

several years in favor of a building for automobiles, but through economy the State has refused to build it.

J. K. Skowlund, a Milwaukee automobile dealer, has opened a school for the instruction of automobile drivers and salesmen.

The Schildwachter Carriage Company, New York city, have opened a salesroom for automobiles in the Thoroughfare Building.

The Wisconsin Automobile Supply Company, Two Rivers, Wis., has enlarged its factory there and is planning to increase its equipment.

The new four story brick and concrete addition to the factory of the F. B. Stearns Company, Cleveland, Ohio, is to be completed by September 15. It measures 120x180 feet.

The Speed Changing Pulley Company, of Anderson, Ind., has changed its name to the De Tamble Motors Company, automobile motors being now the principal line of manufacture of the company.

The contract for the two story, 100x300 feet, reinforced concrete addition to the plant of the Rapid Motor Vehicle Company in Pontiac, Mich., has been let, and the building is to be completed by December 1.

During the week ending August 28 Ford cars led the New York registrations with 55, followed by Packard with 31, Buick 22, Cadillac 22, Maxwell 20, E-M-F 16, Mitchell 13, Studebaker 13, Autocar 12, Franklin 10, etc.

The Stoddard-Dayton Automobile Company, of Philadelphia, have secured new show rooms at 253 North Broad street, where a new building is in course of construction for them. The Courier car will also be handled.

The Garland Automobile Company has been organized to handle Speedwell and Velie cars in New York city, and has secured salesrooms at 1657 Broadway. The officers of the company are G. W. Garland, president; G. P. Strobel, vice president, and John A. Garland, secretary.

#### Club Notes.

A meeting of automobile owners in Shreveport, La., was held at the State fair on August 26, with the object of perfecting the organization of the Shreveport Automobile Association. The call for the meeting was issued by the management of the State fair.

A meeting was held at the Commercial Club in Medford, Ore., on August 24, with the object of organizing an automobile club. It is stated that in Medford and vicinity no less than 180 cars are owned, and considerable interest is being taken in the proposed club.

The Washtenaw A. C. was organized at a meeting held at Ann Arbor, Mich., on August 25th. The following officers were elected: H. W. Douglas, president; R. T. Dobson, vice president, and J. S. Scovel, secretary and treasurer. The club plans to combine all motorists in Washtenaw County.

Meetings will be held the first Tuesday of each month and the annual membership dues have been fixed at \$2.

The New Mexico A. A., Albuquerque, N. M., which is said to have been practically dormant since last spring, is to be revived again, and a meeting was called at the Commercial Club a short time ago, at which new officers were to be elected. The term of the old officers expired last May

The Austin (Tex.) A. C. was organized at a meeting held August 27, in the council chamber of the City Hall, which was attended by about fifty owners of machines. A. C. Goeth was elected temporary chairman and O. E. Millican, temporary secretary. A committee to draft a constitution and bylaws was appointed.

#### Garage Notes.

A fireproof garage building is being erected for the Keystone Garage Co., Norristown, Pa.

Malcolm Stewart has begun the erection of a garage in Hoquiam, Washington, on Seventh street, opposite the City Hall.

The Clark-Pratt Automobile Co. are erecting a garage in Ontario, Ore. It will be a brick structure with cement floor and metal ceiling.

The Kingman-St. Louis Implement Co., who recently secured the agency for Rambler cars, have leased a garage at 2117-2119 North Broadway, St. Louis.

Hicks & Borden have leased the Wentland Building in Charles City, Ia., and plan to open it as a garage. They will handle several lines of low priced cars.

The firm of Newson & Rimes, St. Louis, Mo., have established an automobile repair shop in connection with their tire vulcanizing plant at 4108 Olive street.

L. A. Newman, Auburn, Neb., has sold his garage and automobile business to Geo. Codington and Harry Furlong. The new owners have placed Albert Putnam in charge of the business.

The Mora Sales Co., of Syracuse, N. Y., is being reorganized, Charles J. Roehn having retired from the concern. The company will handle Regal and National cars the coming season.

The Munger Automobile Co., Dallas, Tex., have sold their garage to the Staten-Kicber Auto Co. The garage is located at Jackson and Prather streets. The Staten-Kleber Co. will handle the Mitchell line.

A. J. Pray, formerly a traveling salesman, will open at Fourth and Chestnut streets, Columbus, Ohio, within a week or two, with the agency for the Studebaker line. F. E. Averv has been handling the E.-M.-F. cars.

The Nyberg Automobile Works, 2437-2439 Michigan avenue, Chicago, have added another story to their building, which gives them a total floor space of 30,000 square feet. Mr. Nyberg has taken the agency for the De Tamble Roadster.

An addition is being made to the Regent Garage of Philadelphia, whereby the storage capacity will be doubled. When the alterations are completed the garage will have two entrances, on Baltimore avenue and Springfield avenue, respectively.

The Dayton Motor Car Co. will have a branch house in Seattle, Wash., for the season of 1910, under the management of Ira D. Lundy. Mr. Lundy is now making an effort to find a location for his headquarters. For the last three seasons he has been salesman for the Winton Motor Carriage Co. in Seattle.

The Janesville Motor Car Co., of Janesville, Wis., has started work on the construction of a garage at 140 to 146 North Main street, 44x100 feet in dimensions, two stories high, of brick and stone. The first floor will have no pillars on posts, giving an unobstructed floor space of more than 4,500 square feet. Wilson Lane is president

and treasurer of the company, and Harry Mc-Daniel is secretary and manager.

S. D. Perry will open a garage in Kaneville,

P. M. Shelton is opening a garage at Amarillo, Tex.

The Simplex Automobile Co., New York city, have leased stores at 1862 and 1864 Broadway.

. Ed. Van Lennep and Clarence Willis, Auburn, Cal., have formed a co-partnership and embarked in the automobile business.

The Curtin-Williams Automobile Co., Columbus, Ohio, no longer handle the Premier and the Oldsmobile, but retain the Cadillac.

The Overland Automobile Co.'s branch at Chicago has secured a lease on the property at 2425 Michigan boulevard for a term of fifteen years, on which a new building will be erected.

which a new building will be erected.

W. D. Williams, of Bedford, Ind., and Thomas Meeker, of Indianapolis, Ind., have leased the Rhodus Building on Capitol avenue, Indianapolis, and will shortly open a garage under the style of Williams & Meeker.

Warner M. Bateman, a former newspaper man of Pueblo, Col., has secured the agency for the Studebaker line in San Diego, Cal., and on October 1 will occupy the garage at 1144 First street, now occupied by Leon T. Shettler.

The firm of Olson & Hunter, who represent Winton and Mitchell cars in Oakland, Cal., have had plans prepared for a new 100x125 foot garage building on .Twelfth and Jackson streets. Work on the building will be begun immediately.

Lou Rose has purchased the interest of his partner Dulmage in the Dulmage-Rose Automobile Co., operating a garage in Spokane, Wash., and will continue the business for himself. Mr. Dulmage has accepted the agency for the Studebaker in Portland, Ore., and will open a garage there.

The Vicksburg (Miss.) Automobile Co. has been organized with a capital stock of \$10,000, to start business September 1. The following officers have been elected: J. H. Hempen, president; F. E. O'Neil, vice president; A. J. Martin, treasurer; B. J. Reid, general manager; Lee Richardson, secretary.

The Pioneer Automobile Co., of San Francisco, have leased a property at Van Ness avenue, Mc-Alister street and Ash avenue, with a frontage of 120 feet on Van Ness avenue, and depth of 219 feet. The company plans to erect a three story automobile repository and garage building on the site.

The Coston Automobile Co., Asheville, N. C., which was recently incorporated with a capital stock of \$20,000, and purchased the garage of the Southern Automobile Co. on Patton avenue, has elected the following officers: Dr. C. B. Reynolds, president; Junius G. Adams, vice president, and J. A. Coston, secretary and treasurer. The company will install a repair shop.

C. C. Swinborne and James A. Murray will erect a double garage building on East Quartz street, Butte, Mont. There will be two buildings connected by archways, each occupying a 50 foot lot. The building will be one story high on Quartz street and two stories at the rear, and a repair shop will be located in the basement. The buildings will be of brick and concerete, and will cost about \$20,000.

The E. R. Thomas Motor Co., of Buffalo, have established a branch in Chicago, temporarily located at 1325 Michigan avenue. A new building is now under construction for the branch in Chicago's automobile row, farther out on Michigan avenue. C. T. Paxson, who has had charge of the Thomas retail department in Buffalo since its inception, has been appointed manager of the Chicago branch, and Gaylord Warner, of Kansas City, will be his assistant.

The Portland (Me.) Motor Mart and Garage has been established at 17 to 21 Forest avenue, close to the centre of the city. The proprietors are W. W. Griffin and W. E. Whipple. A number of dealers are said to have taken space in the mart, there being two large salesrooms on the Forest avenue side. In the basement may be stored seventy-five cars and forty-five more on the street floor. The building is provided with an elevator accommodating the largest cars. The Intervator accommodating the largest cars.

state line of cars will be handled. Rosco G. Willard will have charge of the garage.

C. J. Hagensen, of Rochester, Minn., plans to open a garage in Jackson, Tenn., if he can find a suitable building.

Dr. J. W. Hawkins conducts the Barbados Garage at Westbury House, Barbados, West Indies, and also acts as agent for the Ford cara.

J. W. Garland, Jr., of New York city, has secured the agency for Velie cars for New Jersey and for the State of New York, south of Albany.

The Maxwell Agency in Freeno, Cal., of which E. R. Pelts is manager, have secured new head-quarters on I street, containing 7,500 square feet of floor space,

The Selden Motor Car Co., Boston, Mass., has removed from its former location on Boylston street above the railroad bridge, to 801 Boylston street, corner of Fairfield street.

The Ellinwood Disc Sled Co., Ellinwood, Kan., will immediately begin the erection of a single story 50x120 foot garage building, to be completed in two months. The company handles the Mitchell line.

The building at the southeast corner of Jefferson avenue and Randolph street, Detroit, has been remodeled into an up to date automobile salesroom, and is now occupied by the Cunningham Auto Co. They handle the Studebaker lines.

An addition to the O. K. garage at Arcata, Cal., has been completed, and will be used as a machine shop. The dimensions of the shop are 30x45 feet., and the machinery is to be driven by a 2 horse power electric motor.

J. T. Baxter and Mr. Robinson have purchased the repair shop of Midyette & Rushing, Jackson, Tenn., and will remove it on September I from III West Lafayette street to 210 and 212 Shannon street, where they will open a garage in a former livery stable.

W. A. J. Schmelzinger has opened a garage in the rear of 84 Walnut street, Springfield, Mass. The present storage capacity is sufficient for twelve cars, but the garage is to be enlarged so as to house thirty-two. Peter Miller will have charge of the garage.

Milton P. Stiles is erecting a two story 52x100 foot garage building at Ventura, Cal. Only the first floor will be used for garage purposes, however, the second story being fitted up for office purposes. The front and side of the building will be of white pressed brick.

The owners of the Cliff House, San Francisco, Cal. have made an offer to the city to turn over to it the garage building erected in Cliff avenue, on land already owned by the city, without authority from the supervisors. The garage is used by patrons of the ocean resort.

The Superior Motor and Machine Works Co. has been organized at Duluth, Minn., to conduct a garage and automobile agency business on Broadway and Banks avenue, Duluth. The officers of the company are as follows: A. T. Roth, president; Ben. Eimon, vice president, and Dr. H. J. O'Brien, secretary and treasurer.

The Philadelphia branch of the Winton Motor Carriage Co. will be housed in a new building by the first of next year. The building now occupied by the branch at 246 and 248 North Broad street, is to be torn down and replaced by a more modern structure. Temporary quarters will be secured until the new building is completed.

E. Zeller, proprietor of the Palace Hotel, Napa, Cal., has just completed the Palace Garage opposite the hotel on First street. It is a 120x60 foot structure of galvanized iron with cement floor. The equipment includes a mercury rectifier for charging storage batteries and a compressed air plant for the inflation of tires. J. C. Jacobson is manager of the garage.

The Jungclas Automobile Co., of Cincinnati, Ohio, plan to erect a new garage building on Reading road and Maple avenue, Avondale. It is to have a frontage of 71 feet on Reading road, and 150 feet on Maple avenue. The first floor is to contain salesrooms for cars and accessories, as well as stock rooms, and there will be two driving entrances on Reading road and one on Maple avenue. On the second floor will be the offices.

chauffeurs' room, ladies' waiting room, supply room, etc.

Booth & Dexter, of Parker, S. Dak., have bought the repair shop established by Koeppe & Hunt in Gettysburg, S. Dak.

James Healey, Carthage, Mo., has purchased a property on Chestnut street between Second and Third streets, on which he will erect a two story garage building.

The Crown Auto Co., who handle the Cadillac car in Cincinnati, Ohio, have recently moved from 108 West Court street to larger quarters at 2624 and 2626 Reading road.

The Rystrom Implement Co., of Stromsburgh, Neb., have purchased a lot adjacent to their implement building, on which they will immediately erect a 25x100 foot cement block garage building.

The Brush-Chicago Co. are planning to erect a new four story building on Chicago's automobile row on lower Michigan avenue, to be completed by November 1. Architects are now at work on the plans.

The new garage of the Totten Auto Co., Rock Island, Ill., located on Third avenue and Seventeenth street, has been opened for business. The garage contains a repair shop, and has facilities for charging storage batteries and vulcanizing tires.

The Bennett Auto Supply Co., Sioux City, Ia., are adding two stories to their building in Nebraska street, making it a four story structure. The third story will be used as a stock department for the supply store, and the top floor will be given over to a machine shop.

A new garage building is being erected for H. C. Goodchild on East Main street, Salem, Ohio. It will be a single story structure 30x103 feet, with a fancy concrete front and entrances at both the front and rear. The garage will have a cement floor and a repair shop in the rear.

Smith & Morgan, Youngstown, Ohio, will erect a garage building in East Boardman street. The building will be of brick and stone, with a frontage of 50 feet and a depth of 65 feet. It will be two stories high with a basement. The ground floor will serve as a storage room, and a repair shop will be fitted up on the second floor.

Plans have been drawn for a six story and basement reinforced concrete automobile building on Twenty-fifth street, Chicago, between Michigan and Wabash avenues. The building has already been leased to an automobile concern for term of twenty years. The plot measures 62½x110 feet, and the cost of the building is estimated at \$75,000.

A new fireproof concrete and steel garage is nearing completion at 73 Washington square South, New York city. It has 63 foot frontage, and is L shaped, being 52 feet deep on one side, and 96 feet on the other. There are three floors and a basement. The building is provided with an elevator, two turntables, two washstands and an air compressor.

#### New Incorporations.

The Pyramid Motor Car Co., of Danbury, Conn., has filed notice of an increase in capital stock from \$10,000 to \$100,000.

Marquette Motor Vehicle Co., Chicago, Ill.— Capital stock, \$20,000. Incorporators, Isaak L. Marks and David J. Marks.

Houston Motor Car Co., Houston, Tex.—Capital stock, \$10,000. Incorporators, E. T. Barden, H. D. Ellis and O. E. Coverdill.

Ogden Wind Shield Co., Chicago, Ill.—Capital stock, \$2,500. Incorporators, Henry P. Sinden, Sirell R. Janius and Karel E. Rada.

Olds-Oakland Automobile Co. of Texas, Houston, Tex.—Capital stock, \$10,000. Incorporators, C. F. Gydeson, Robt. Druschke and N. B. Jedd.

The Economy Motor Car Co., East Cleveland, Ohio.—Capital stock, \$10,000. Incorporators, Willis E. White, Frank T. Corell, O. E. Smith, C. H. Clark and W. W. Clark.

The Aberdeen and Hoquiam Transportation Co., Aberdeen, Wash.—Capital stock, \$35,000. Incorporators, C. G. Palmberg, Albin W. Norblad, G. A. Hemple and Thos, Toivonen, of Astoria, Ore.; C. E. Reikki, of Houghton, Mich., and John Olin, of Chinook, Wash.
Imperial Motor Co., of Kansas City.—Capital,

Imperial Motor Co., of Kansas City.—Capital, \$20,000. Incorporators, W. F. Tuttle, G. V. Dodge, Gail Reed.

Holly Motor Co., Seattle, Wash.—Capital stock, \$10,000. Incorporators, John C. Hollingsworth and John A. Lane.

The Miller Motor Co., Milwaukee, Wis.—Capital stock, \$20,000. Incorporators, H. C. Mueller, J. Hirsch and Peter Barth.

United Motors Co., Chicago, Ill.—Capital stock, \$5,000. Incorporators, William F. Gray, George I. Derr and D. B. Cole.

The Fenimore Garage Co., Yonkers, N. Y.— Capital stock, \$2,500. Incorporators, Jos. Haight, E. J. Dalton and E. J. Larkin. The Motor Service Co., Camden, N. J.—Capital

stock, \$100,000. Incorporators, Harvey L. Lechner, Doering Bellinger and W. G. Jones.

Elmore Motor Car Co., Los Angeles, Cal.— Capital stock, \$75,000. Incorporators, E. B. Smith, D. B. Rose and Clarence F. Smith.

Helena Auto Co., of Helena, Okla.—Capital stock,, \$2,000. Incorporators, C. N. Brewer, J. G. McCulley and C. H. McCulley, all of Helena.

An amendment has been filed by the Battery Light and Power Co., of Milwaukee, decreasing the capital of the concern from \$25,000 to \$15,000.

Pueblo Auto Goods Co., Pueblo, Col.—Capital stock, \$10,000. Incorporators, W. H. Bullen, L. G. Walker, R. E. Cruzen and William Anderson. American Automobile Co., St. Joseph, Mo.—Capital stock, \$25,000. Incorporators, W. G. Campbell, John F. Garber, C. R. Vaughn and others.

Jackson City Garage, Jackson, Cal.—Capital stock, \$10,000. Incorporators, Henry Thorpe, Joseph J. Ratto, P. Marcucci, John Strohm, George W. Lucot.

The Hinton Automobile and Supply Co., Hinton, W. Wa.—Capital stock, \$2,500. Incorporators, C. C. Coalter, John Leslie, C. W. Garrett and W. L. Fredeking.

Queen Colony Garage, Corona, Cal.—Capital stock, \$10,000. Incorporators, James L. Davis, W. C. Barth, John P. Triolo, W. E. Hetfield and O. A. Huxsaw.

The Woods Engineering Co., Alliance, Ohio.— Capital stock, \$30,000. Incorporators, F. C. Woods, F. A. Woods, F. A. Hobbs, W. C. Brown and H. H. Woods. The Little Rock Taxicab and Transfer Co.,

The Little Rock Taxicab and Transfer Co., Memphis, Tenn.—Capital stock, \$20,000. Incorporators, Louis Wolfort, L. Reinman, Alfred Mayer and C. S. Wolfort.

The Blevins-Studebaker Auto Co., Toledo, Ohio.
—Capital stock, \$10,000. Incorporators, H. W.
Blevins, C. P. Lauchmans, T. E. Coles, F. W.
Caughling and P. F. Parrot.

Auto Transit Co., Covington, Ky.—Capital. \$3,000. Incorporators, L. Hill, Jr.; J. M. Morrison, John Craig, Thomas Anderson, J. M. Polk, T. O. Gibbs, J. B. Sandford.

The Cataract Motor Co., Paterson, N. J.—Capital stock, \$350,000. Incorporators, Louis A. Piaget, Wm. H. Sherman, Foster W. Freeman, Geo. F. Hannah and Harris J. Westerhoff,

The E. R. Thomas Motor-Branch Co., Boston, Mass.—Capital stock, \$100,000. Incorporators, E. L. Thomas, president; J. M. Edsall, secretary and treasurer: C. S. Henshaw, manager.

Ohio Motor Co., Carthage, Hamilton County, Ohio.—Capital stock, \$10,000. Incorporators, Chas. F. Pratt, James W. McCutcheon, Albert E. Schafer, Lewis L. Townley and Ida A. Pratt.

The Eddy-Sherwood Carriage and Motor Co., Bridgeport, Conn.—Capital stock, \$5,000. Incorporators, Henry Sherwood, of Fairfield; George E. Eddy, of Bridgeport, and George S. Jennings, of Southport.

A. D. Goetz Co., Charlestown, W. Va.—To manufacture harness, saddlery, automobiles, etc. Capital stock, \$25,000. Incorporators, A. D. Goetz, Geo. B. Goetz, Hiram A. Goetz, Maria A. Goetz and Jenny S. Goetz.

The Allen Taxicab Co., New York City.—Capital stock, \$1,000,000. Incorporators, A. E. Wilson, Geo. A. K. Sutton, Geo. E. Holmes, Thos. F.

Barrett and Kenneth K. McLaren, all of 37 Wall street, New York city.

The Aberdeen and Hoquiam Transportation Co., Hoquiam, Wash.—Capital stock, \$35,000. Incorporators, C. G. Palmberg, Albin W. Norblad, C. A. Henkle and Thos. Toivonen.

#### Trade Personals.

G. M. McGreggor, secretary and treasurer of the Ford Motor Co. of Canada, left on August 26 for Australia, where he will open a Ford branch

Felix A. Eisner, M. E., sailed for Europe Thursday on the George Washington, of the Hamburg Line, in the interest of the E. R. Thomas Motor Company.

G. A. Malcomson, of Chatham, Ont., has been appointed to the position of manager of the Ford Co. of Canada, which will shortly be established at Winnipeg, Man.

H. L. Center, who recently sold his interest in the Ollinger-Center Motor Car Co. in Salina, Kan., has been appointed assistant to the general manager of the Buick Texas branch, with headquarters

S. W. Rushmore sailed on the Mauretania last week for a six weeks' tour in Europe. Mr. Rush-more plans to establish a branch of the Rushmore Dynamo Works in Berlin, and will visit the existing branches in London, Paris and Milan.

D. E. Simmons, of Beloit, Wis., has accepted the position of a superintendent in the factory of the Mitchell Motor Car Co. of Racine, Wis. Simmons was formerly foreman of the polishing department of the Fairbanks-Morse Co. of Beloit.

Walter G. Morley, who in the past has been connected with the Olds Motor Works and the Aerocar Co., and who more recently acted as manager of the Canadian branch of the Reo Motor Co., has connected himself with the Ford Motor Co. as purchasing agent, succeeding H. C. Limbach,

O. S. Tweedy, who for many years was manager of the Chicago branch of the Diamond Rubber Co., and more recently was connected with the Federal Rubber Co., has been appointed sales manager of the Continental Caoutchouc Co. of New York, E. E. McMasters and I. H. Sheldon have been appointed district sales managers for the West and East, respectively.

E. Leroy Pelletier, formerly advertising manager of the Everitt-Metzger-Flanders Co., of Detroit, has been appointed general advertising manager of Studebaker Automobile Co. and Studebaker Brothers Manufacturing Co., with headquarters at South Bend, Ind. In his new capacity Mr. Pelletier will have full control of all advertising of Studebaker horse drawn vehicles and the full line of automobiles handled by the Studebaker Co.

### Patents Issued July 20, 1909.

928,334. Pneumatic Tire.-Robert J. Ruths, Baltimore, Md. Filed September 10, 1908.

1. A tire consisting of a tube and a cover, a tread ring and a grip ring secured to the cover. layers of material covering the tire, the tread and the grip, a continuous metal sheet covering the entire tread, and spikes passing through the metal into the tread with their heads protruding.

928,433. Pneumatic Tire Armor.—Charles E. Evans, Council Bluffs, Iowa. Filed February 7, 1908. (Chain type.)

928,520. Anti-Vibration Device for Vehicles of Any Kind.—Georges Huysmans, Brussels, Belgium. Filed December 23, 1908. (Rubber air cushion between frame and body.)

928,611. Vehicle Tire .- William A. Köneman, Cudahy, Wis. Filed June 22, 1908. (Sectional

inner tube.)
928,731. Vehicle Tire.—Martin Lehrer, New
York, N. Y. Filed August 16, 1907. (Armored strip between inner tube and casing.)

928.868. Non-skid Tire.—Eleazer Kemnshall. London, England, assignor to Kempshall Tyre Company of Europe, Limited, London, England. Filed November 5, 1907.

928,848. Traction Wheel.-Newton Campbell, Elizabethtown, Ohio, assignor of one-fourth to Harry J. Sykes and one-fourth to Joseph W. Hayes, Elizabethtown, Ohio, and one-fourth to George H. Wilson, Cleves, Ohio. Filed April 18, 1908. (Spring plunger tread.)

928,486. Variable Speed Gear.—Herbert E. Williams, Portsmouth, England. Filed January 27, 1008.

928,648. Speed Changing Mechanism.,-Walter O. Foss, Philadelphia, Pa., assignor to Frederick C. Brunhouse, Philadelphia, Pa. Filed September 11, 1908.

028.568. Variable Speed Gearing.-William A. Widmer, Danbury, Conn. Filed March 17, 1909. (For motorcycles.)

928,705. Changeable Speed Gearing.-Walter Scott, Sheridan, Wyo. Filed December 10, 1908. (Parallel driving and driven shafts with gears not meshing. An intermediate gear and mechanism for shifting it to connect successive gear pairs.) 928,727. Speed Controlling Mechanism.—Austin M. Wolf, New York, N. Y. Filed July 11, 1908. (Two speed and reverse spur gear and two pairs of bevel gears, giving four speeds and reverse.) 928.739. Friction Drive Mechanism for Auto mobiles.-Albert B. Cole, St. Louis, Mo. Filed

November 23, 1908. (Cone and bevel type.) Internal Combustion Engine.-Emile 928,842. Berliner, Washington, D. C. Filed March 31,

1909. (Valve gear details.) 928,715. Engine.—Thomas A. Thurber, Stockton, Cal. Filed March 1, 1907. (Revolver type driving through cam.)

928,824. Circuit Closer .- Orville M. Tustison, Bainbridge, Ind. Filed June 30, 1908. (Key operated switch for coils.)

928,790. Automobile Fifth Wheel .- Evertt A. Oliver, Richland, Mo. Filed May 18, 1908.

928,800. Roller Bearing.—August Schilling, Berlin, Germany. Filed October 24, 1907.

928,803. Fuel for Internal Combustion Engines.—George B. Selden, Rochester, N. Y. Filed December 7, 1903. Serial No. 184,083. Renewed May 13, 1909.

The combination with a suitable liquid hydrocarbon, of picrate of naphthalene and peroxide of

hydrogen, substantially as described.
928,828. Carburetor.—Alexander Winton, Cleveland, Ohio. Filed April 9, 1907. Serial No. 367,215.

### Patents Issued July 27, 1909.

928.954. Transmission Gearing.—George Flessa, Rawhide, Nev.

Disc friction.

928,955. Automobile Propelled Vessel.—John W. Freeman, Joplin, Mo.

928,956. Anti-Friction Bearing.—Heinrich Froböse, Bielefeld, Germany.

Ball separator for annular type bearing.

928,968. Explosion Engine.-Bertron G. Harley, Pittsburg, Pa.

Two cycle.

929,100. Governed Pump.—Norman McCarty, Indianapolis, Ind. Fuel pumps.

Gregor, Duluth, Minn.
929,193. Cover for Pneumatic and Like Tires.—

Henry W. Cave-Browne-Cave, London, England. Non-skidding tread.

929,197. Headlight for Vehicles.—Arthur E. Dobbs, Winona, Minn.

929,203. Tire Shield .- Joseph H. Fletcher, Seattle, Wash.

Rivet filled tread.

929,208. Wheel.-Leonard J. Goodspeed, Rockford, Ill.

Wheel .- Frederic R. Mather, Whites-929,234. ville, N. Y.

Detachable rim

929,262. Electric Igniter for Explosion En gines.-Walter C. Thornhill, Minneapolis, Minn. Make and break piston operated.

929,260. Carburetor.-John W. Stevens, St. Paul. Minn.

Carburetor .- Bert Rinke, Detroit, 929,327.

929,331. Storm Front for Vehicles.-George W. Scott, Troy, Ohio.

920.351. Pneumatic Tire.-Paul I. Viel. Paris. France.

Air Compressing Pump.—Sven Dahlberg, Springfield, Mass.

929,418. Tire.-George H. Gillette, New York,

Cushion inner tube.

929,425. Variable Speed Gearing.—Joseph Heim, Winnipeg, Man., Canada.

Multiple bevel gear.

929,426. Ball Bearing.-Fritz Henzelmann, Chicago, Ill.

Intermediate spacing balls.

929.427. Anti-Friction Bearing.-Fritz Henzelmann, Chicago, Ill.

Ball separator.

Pneumatically Operated Ignition De-929,429. vice for Gas Engines.-Charles G. Hess, Center, Col.

Make and break.

929,437. Vehicle Wheel.—William L. Howard, Trenton, N. J. Detachable rim.

929,484. Piston Packing Ring.-Ernest W. Petter, London, England. 929,503. Fuel.-George B. Selden, Rochester.

N. Y.

Claim 4. As an improved fuel for internal ignition engines, a liquid hydrocarbon containing peroxide of hydrogen and a nitro-substitution comnound, substantially as described.

929,540. Reversible Petroleum and Compressed Air Motor .- Marius Berliet, Lyon, France.

929,556. Power Transmission Mechanism. liam G. Clifton, Highbury, London, England.

929,582. Electric Current Rectifier .- Eugene Garretson, Buffalo, N. Y.

An electric current rectifier comprising a body of silver sulphide and a body of metallic oxide in electrical contact therewith.

929,588. Self Starting Device for Gas Engines. -William A. Hansen, San Francisco, Cal.

Compressed air.

929,605. Safety Steering Attachment for Automobiles.-Henry P. Larouette, San José, Cal.

929,620. Tire.-George E. Miller, Newton Center, and Carl M. Wheaton, Newtonville, Mar 929,622. Explosive Engine.-Isaac G. Neuber.

Detroit, Mich. Two cycle.

929,627. Mask for Automobile Lamps.-Harold D. Penney, Brooklyn, N. Y.

Tire Tread.-Joseph R. Sanford and 929.632. John G. Doughty, Winsted, Conn.

A tire tread having a multitude of air chambers formed within and thereon, the major portion of each air chamber being formed by walls of circular cross section.

**VOLUME XXIV** 

NEW YORK, SEPTEMBER 15, 1909

NUMBER 11

### Boston as a Centre of the Motor Express Business.

By H. H. Brown.

Perhaps one of the most interesting and profitable applications of the motor vehicle in commercial work in the vicinity of Boston is in the service of regular express companies for the transportation of goods to and from surrounding towns. There are at least a dozen regular express companies which employ motor trucks to transport goods from the city to the town in which they operate, delivering and collecting at either end by single one horse wagons in most cases. The lengths of the routes vary from 5 to 20 miles, and from one to three round trips are made daily on practically regular schedule time.

Practically all of the concerns employing motor trucks for this purpose are old firms which have been in the express business for years, and which formerly employed horses in the same manner in which the motor trucks are now employed. In most cases a single truck was put on as an experiment, and after a thorough trial, in some cases of a year or more, the first order was followed by a second, and, in at least one case, by a third.

The following partial list of the towns to which motor express services run from Boston will give anyone acquainted with Boston and its suburbs a fair idea of the magnitude of the business. The figure after a town signifies the number of companies operating automobile express routes to the town from Boston: Lynn (2), Swampscott, Salem, Malden, Waltham (2), Watertown (2), Newton, Mattapan, Medfield, Quincy, East Weymouth.

#### LOAD TRANSFER POINTS.

Goods are delivered to and collected from the trucks by one horse delivery wagons in Boston, mostly at certain squares and streets, as permitted by the street traffic regulations. The principal points used for this purpose are Haymarket square, the lower end of State street, near the Custom House, and Providence street, between Park square and Berkley street, although one or two companies have intown depots at the express platforms at the North Station. In certain cases where a consignment of goods from one party to another constitutes more than a quarter of the total load of a truck. there is often a saving in time, as well as of labor, in rehandling, by direct delivery from door to door entirely by truck. The work done by the machines covering different routes varies quite a little, owing to the varying lengths of the routes and the practical limitation of the length of the working day. This may be made plainer by means of a few practical examples.

Let us take the case of Weiker's Medfield Express. From Boston to Medfield is about 25 miles, and the round trip is therefore about 50 miles. Now, considering the time taken to load and unload, it will be seen that it is impractical to make more than one round trip per day, nor is it practical to make arrangements for garaging at both ends of the line, everything considered. Hence the truck in this case is not working to its best advantage. On the other hand, take the case of Cushing's East Weymouth Express. This covers a route of from 15 to 18 miles, and makes two round trips per day. Thus in this case the mileage is from 60 to 70 per day. In the same way the length of the route alters the balance in favor of the motor truck when compared with horses, although in all cases the showing is favorable to the truck. The majority of the trucks carry from one and one-half times

to twice the load of the two horse wagons which were formerly employed for this purpose, and average from 10 to 12 miles per hour, as against not over 5 to 6 miles per hour for the horse wagons. The maximum average daily mileage of the horse wagons was not over 20, as compared with about 70 for the truck. Besides this, considerable has been saved in stable charges at the Boston end of the routes in many cases.

#### TYPES OF TRUCKS.

Thus far no electric trucks have been employed in this line of work in the vicinity of Boston, and with one exception all the machines employed are of the internal combustion type. This exception is a Stanley steamer, operated by Newcomb's Express, which runs from Boston to Newton over a route of about 7 miles. As this car is the only one of its type thus far in operation a description may be of interest. The motor is a two cylinder, double acting engine of the well known Stanley type, mounted on the live rear axle and driving the same by means of a single reduction spur gearing. The boiler is 26 inches in diameter and is mounted in front under the hood. The truck is rated at 3,000 pounds capacity, although it is frequently loaded to much more than this. It is fitted with pneumatic tires, 36x51/2 inch rear and 36x41/2 inch front. The tires now on the wheels have seen about 4,500 miles of service. The machine consumes from 12 to 15 gallons of gasoline per day, according to the load carried, and whether two or three trips are made. To offset this somewhat excessive consumption of gasoline it is claimed that very little oil is required, and that the upkeep expenses for repairs are quite low.

#### ABBOTT & MILLER'S EXPRESS.

Perhaps one of the most interesting developments of the motor express business in the city of Boston is the service of Ab-

NEWCOMB'S EXPRESS.

FOUR TON TRUCK OF THE MOTOR TRANSPORTATION COMPANY.

ABBOTT & MILLER'S GARAGE AT QUINCY.

bott & Miller, who have for years run an express from Boston to Quincy. This firm formerly employed horses. About two years ago they commenced to see the possibilities of the motor truck in their business, and it was decided to experiment with one, after carefully looking the field over.

Their first truck was used for six months. making two round trips per day, or an average of 44 miles per day. At the end of that time a second truck of the same make was purchased and the first laid off for overhauling. A third truck of the same make has recently been added to the equipment. This firm realizes that no matter how perfect a machine may be it is in the nature of things that certain parts wear out or break and require replacement, and they therefore decided to put in a repair shop and do all their own repair work, thus saving delays and considerable expense. They accordingly fitted up part of their garage as a machine shop, putting in an engine lathe, an upright drill, a shaper, a power hack and an emery wheel Besides this, there are a blacksmith's forge and an inspection pit, and electric portable drills form part of the shop equipment. A good supply of the parts most frequently worn out or broken is kept on hand, such as chains, sprockets. springs, etc. Two machinists are constantly employed in the shop. These are kept steadily employed, as it has been found that considerable outside work may be obtained. This firm, after having proven to its satisfaction that through trucking was a success, saw the possibility of making a success of delivery work right within the city. They accordingly took the agency for another make

of commercial wagon and put ten delivery wagons of this make on one of their routes. This route is 23 miles in length, and was formerly covered by a one horse wagon once per day. The motor truck makes three round trips, with an average of fifty stops per trip.

#### RESERVE STOCK RULE.

Besides the four machines used in the regular express service, a fifth machine is in use. This is made over from a two cylinder runabout, which was fitted with a small box body in the rear. This machine is sometimes pressed into service as an emergency delivery wagon, but it is mostly used as a repair wagon when some breakdown occurs to a truck, which may be mended on the road, as, for instance, the breaking of a spring. The garage of this concern is a one story building, heated by steam, with the repair shop at one side. The flooring of the main part is of dirt, although there is a concrete floored washstand to one side, One thing that has been brought out by the experience of this firm is the importance of having a reserve truck in order to have a machine to put in service in case of a breakdown or when one of the trucks needs a general overhauling.

The observations of this firm, combined with their own experience, lead them to the belief that a reserve of one machine for every five machines in active service is about the right proportion. This seems to be also the opinion of other firms using commercial vehicles of one sort or another. Another thing that has been brought out is the extreme desirability of having the machines of one make, and as far as possible inter-

changeable. This point was recently very strikingly illustrated by the following incident: One of the machines was undergoing its periodical overhauling, which, by the way, is very thorough, the chassis being stripped to almost the last nut and bolt. To assemble the machine and put it in operating condition was the work of at least a week. One afternoon one of the trucks which was then in operation broke a crank shaft. As soon as the other truck delivered its load it was sent out after the disabled one, which was then towed to the office. unloaded, and then towed to the garage. The crank shaft of the machine which was being overhauled was then substituted for the broken one, the machinists working all night. The result was that the disabled truck was in service again the next day. Had the trucks been of different makes or not interchangeable it is probable that a week's delay would have resulted.

#### SHIFTING OF LOADS.

While most of the express companies have depots or stables in their towns where the loads may be shifted from the motor trucks. either to a loading platform or directly to the delivery or collecting horse wagons, only a single one of the companies has a Boston depot. In most cases the shifting of loads is done directly from the truck to the horse wagon, and vice versa, on certain streets and squares, as permitted by the traffic regulations of the city. The principal points where this is done are as follows: The Malden Auto Express and Nally's Watertown Express do most of their shifting on Haymarket square; Abbott & Miller do their shifting at Post Office square, Probably the principal point of load transference is at the foot of State street, near the water front; here Weiker's Medfield Express, who cover one of the longest routes, do most of their shifting, as well as Hapgood's Lynn Express. This point is also the principal point for the shifting of the horse drawn loads, and at almost any time of the day at least twenty wagons may be seen shifting their loads or waiting to receive or discharge a load. Providence street is quite a centre for the shifting of loads of those expresses doing business to the south and west of the city. Among these are Newcomb's Newton Express and Jenkin's Mattapan Express. This concern has had a Packard two cylinder truck in service for about a year. This was perhaps the first truck of this make which was used

HAPGOOD'S LYNN AND BOSTON EXPRESS.

in the city, having been used by a wholesale furniture house for about three years and disposed of by this firm in order to buy a larger and more powerful truck of the same make. This fact is interesting, as giving something of a line on the wearing qualities of a good machine.

A few firms make use of the express platforms at the North Stations for the shifting of their loads. These are mostly firms which do considerable railroad work. Among them are Gibb's Waltham Express and Eaton's Wakefield Express. Both of these firms have but one truck in operation, and depend to a certain extent on the railroad for their through hauls,

#### THE MOTOR TRANSPORTATION COMPANY,

The business of the Motor Transportation Company is quite interesting in many ways, as it has many points of difference from the regular motor express business around Boston. In the first place, the home office of this company is Boston, and they have a depot located at their office at 259 Atlantic avenue, where the horse drawn tels direct. It has been found that it is possible for this truck to pick up a return load of shoes and other merchandise at Lynn. Twice a week a truck runs from the Boston depot of a spring water concern to their spring, situated in Lexington, Mass., a run of about 10 miles, carrying out the empties and returning with full carboys of water

Many movers of safes, machinery, furniture and bric-à-brac, the proper moving and packing of which is almost a trade in itself, have begun to realize the possibilities of extending their business to the long hauls made possible by the motor truck, but for various reasons they do not feel justified in investing capital in machines of their own. This firm stands ready to let its truck for this sort of service, furnishing the same with driver for a flat rate per day. Many firms have already availed themselves of this service, to the mutual advantage of both parties.

Outside of the regular express business, there are at least three firms who make a

Io o'clock in the morning, and a grand piano was lowered from the third story window into the 3 ton truck. Then, with the assistance of the packers, both trucks were loaded and ready to start at about 12 o'clock. The two truck loads would have made at least three two-horse loads. The machines were able to run to Ipswich, deliver their loads and return to Boston the same night, ready for another job the next day.

To do the same work three horse teams would have been required. It would have been necessary to have left them over night at Ipswich, the whole next day would have been taken up in returning to Boston, and it would certainly have been advisable to have laid off the horses for another day to rest them up.

Thus it will be seen that two motor trucks in this instance were able to do three times the work of three two horse teams. On the other hand, if the shipment had been by rail, it would, of course, have been necessary to pack much more carefully and thoroughly, and the goods would have had

WARNER & Co.'s Two Trucks Loaded for a Trip to Ipswich.

MALDEN AUTO EXPRESS TRUCK LOADED AT HAYMARKET SOUARE.

wagons deliver and collect the loads from the trucks. Again, this company was organized only quite recently for the purpose of doing an auto trucking business, but it is under the management of experienced, practical express men. At present the company have four Alden Sampson trucks in operation, of 4 tons capacity each. As far as could be ascertained, these trucks are the heaviest so far used in the express business around Boston, none of the other makes being rated at over 3 tons, while these are very conservatively rated at 4 tons. The motors are rated at 40 horse power, having four 5x51/2 inch cylinders. This company does not confine itself to any one line of the express business, although it runs a regular line from Boston to Lynn. making two trips daily, for which one car is amply sufficient.

# SERVICE TO SUMMER HOTELS.
